THE 2021 CROP YEAR IN REVIEW

It seems that every year this publication begins with “The (insert year here) growing season was far from normal.” So, to keep on trend, the 2021 growing season was far from normal. Different challenges are faced by growers every year, and this one was no different. The year started off with the “big rain” in April, with up to 8” of rain being recorded in some places across Georgia. The time was right for cotton planting, but this slowed things down for growers, as some needed to rebed land and repair washes. Following this, May 11 was the last rain shower for many across the state until the first week of June. And once it started raining in June, it didn’t feel like it stopped until October. This year was odd in that the cotton that looked bad was overwatered, whereas in a “normal” year it would be burnt up from dry and hot weather. Much of the cotton was planted in June for many reasons: the first was that some were waiting on the rain to plant, and the second was that wheat acres were much higher in Georgia this past winter and cotton was the preferred crop to double crop behind wheat in most cases. These things and others led to a large portion of our crop being fairly late. However, harvest conditions in 2021 have been absolutely incredible, with most of October being dry and sunny. Thus, when growers were able to harvest they were able to do so across a large number of acres.

It is predicted by USDA that Georgia growers will wind up harvesting 1,170,000 acres of cotton, which places Georgia as clearly the 2nd largest cotton producing state in the United States, second only to Texas. Georgia producers have long remained committed to planting cotton compared to other states across the belt as Georgia had at least twice as many acres as every other cotton state.

Table 1. Average Acreage and Production in Georgia Since 1980.

Time Period	Planted Acreage (x 1,000, Acres)	Yield (lb/A)	Total Bales (x 1,000, 480-lb Bales)
1980-1985	177	564	207
1986-1990	289	573	328
1991-1995	778	729	1,135
1996-2000	1,424	628	1,754
2001-2005	1,350	717	1,969
2006-2010	1,140	835	1,941
2011-2015	1,354	915	2,504
2016	1,180	898	2,180
2017	1,280	841	2,225
2018	1,430	719	1,955
2019	1,380	953	2,740
2020	1,190	887	2,208
2021	1,170	952	2,320

USDA NASS Quick Stats. www.nass.usda.gov. 2021 information forecasted December 1, 2021.

As mentioned earlier, this year was abnormal in that we received what some would say is too much rain. Weather stations at each on-farm variety trial recorded that from planting to harvest, there was between 30 to 35 inches of rain accumulated. In 2020 in Tifton, there was right around 21 inches of rain from May 1 to October 31, just as a comparison. Depending on the area of the state, yields have been all over the board. In fields where there is a relatively high water table and little drainage, yields

were low. Boll rot and foliar diseases were more widespread this year. With respect to many pesticides, growth regulators, and even fertilizer, it was difficult to get in the field to make these applications due to continuous rain. The Southwest part of Georgia seemed to be more negatively impacted by these issues. Southeast Georgia got a little less rain, but their rains were more timely. Overall, dryland yields were above average and irrigated yields were below average. Additionally, yields in East Georgia seem to be higher than those in Southwest Georgia.

The harvest season weather during 2021 has been incredible. Generally things were delayed because of the general lateness of the crop, but also since peanut harvest was delayed due to weather, cotton harvest was also delayed. Extended periods of wet conditions during August and September affected fiber quality to some extent while variety has also played a role. At the time of this publication, not all ginnings are completed, but based on USDA estimates Georgia will produce a crop with an average yield of around 952 lb/A.

Figure 1. Georgia’s state-wide average yield (lbs/A) and harvested acres over the past 21 years. (USDA NASS)

The overall quality of the cotton crop in Georgia in 2021 could be considered good to excellent (Table 2). Staple and uniformity are down slightly, which can be attributed to both environment and variety. In Georgia, variety selection and harvest timing are the two main factors which impact fiber quality. Georgia producers continue to plant varieties that have high yield potential and great fiber quality, although some of the newer, higher yielding varieties may suffer relative to fiber quality. Thankfully,

Georgia growers did not have many extraneous matter issues in 2021. Color grades were good considering the amount of rainfall in August and September. Color grades were down from 2016 and 2017 which had excellent harvest seasons. Average micronaire was 4.4 and less than 3 percent of bales were discounted for high levels. Fiber length averaged 36.69, which is down slightly from 2020. Fiber strength averaged 29.93. Uniformity is down slightly, and the lowest since 2009 averaging 80.86. As mentioned earlier, these fiber quality parameters are a function of environment and variety. Fiber quality should be taken into account during variety selection decisions.

Table 2. Fiber Quality of Bales Classed at the Macon USDA Classing Office, 2008-2020

Year	Color Grade 31/41 or better (% of crop)	Bark/ Grass/ Prep (% of crop)	Staple (32nds)	Strength (g/tex)	Micronaire	Uniformity
2008	25 / 93	all < 1.0	34	28.7	4.6	80.2
2009	26 / 96	all < 1.0	35	28.8	4.5	80.3
2010	50 / 90	all < 1.0	35	29.9	4.8	81
2011	38 / 84	3.0 / <1 / 1.0	36	29.6	4.6	81.7

Economic Situation and 2022 Market Outlook

The 2021 cotton harvest combined both good yields and good prices, which is rare for cotton producers. After the pandemic unfolded, cotton markets have been on an upward trajectory since April 2020, with a recovery of futures prices from the low 50 cents per pound to a high of \$1.22 per pound on November 2, 2021. This recovery of cotton prices is contributed to the global economic

recovery, leading to a recovery of global cotton demand. In addition, the inflation pressure, increasing prices for synthetic fiber, and speculation purchases in the cotton future market also contributed to the rising of cotton prices. Looking ahead to 2022, producers need to be aware of the increase in uncertainty and price risks for cotton and inputs. Factors influencing 2022 cotton prices and profitability include subsequent waves of COVID-19, global economic growth and inflation, trade situation, and the rising of input prices.

Economic Recovery

Cotton products are discretionary items, and thus, cotton consumption follows the trend of the global economy. According to the World Economic Outlook released by Organization for Economic Cooperation and Development (OECD) in October 2021, after a sharp decline of 3.1% in the global economy in 2020, global gross domestic product (GDP) rose 5.9% in 2021, and is projected to continue rising 4.9% in 2022. Similar economic recovery is also observed in the United States. Real GDP in the U.S. increased an annual rate of 0.5% in 2020, which was better than anticipated after a 5.1% decline in the first quarter and a 31.2% decline in the second quarter of 2020 (<https://fred.stlouisfed.org/series/A191RL1Q225SBEA>). The economic recovery in the U.S. slows down in the third quarter of 2020, with a 4.5%, 6.3%, 6.7%, and 2.1% for each quarter since. But it was still faster economic growth than the pre-pandemic level in the United States. This economic recovery at home and abroad created the foundation for price recovery for cotton.

Cotton Supply and Demand

The November 2021 USDA World Agricultural Supply and Demand Estimates (WASDE) report projected U.S. cotton production at 18.2 million bales for 2021/2022 marketing year, slightly over the U.S. cotton demand – 15.5 million bales of exports and 2.5 million bales of domestic mill use. The U.S. planted acreage for upland cotton was forecast at 11.1 million acres. In 2021, the national yield level is at 874 pounds per acre, which is the second-highest on record. U.S. ending stocks are projected at 3.4 million bales in 2021. The U.S. ending stocks-to-use ratio is forecast at 18.9 percent for the 2021/22 marketing year, slightly above last season but below each of the previous three years.

Globally, 2021 cotton production is projected at 121.8 million bales, which is 9.6 million bales greater than last year (Figure 2). World cotton mill use is projected slightly higher than production at 124.1 million bales, 3.2 million bales above last season, and the second-largest on record.

Figure 2. World Cotton Supply and Demand. Data Source: USDA FAS.

Rising in Price Risks

Historically, cotton prices tend to follow the stock market, with a rise in cotton prices when the stock market rises and a decline in cotton prices when the stock market drops. However, since September of 2021, the stock market has been on a roller coaster ride with ups and downs. This roller coaster ride of the stock market created uncertainties for investors concerning the next price drop of the stock market. Some investors pull their money out of the stock market, seeking the next opportunity for a short-term gain.

Under these circumstances, other markets, such as the cotton futures market, experience an inflow of speculative money, pushing prices higher. This probably is the major reason why cotton prices skyrocketed in October and November of 2021, with December 2021 Future Prices rising from the mid-90 cents per pound to a high of 121.67 cents per pound on November 2, 2021. This flow of money into cotton markets has pushed prices to levels that exceed those indicated by supply and demand fundamentals, creating a potential marketing opportunity for cotton producers.

However, money flow in and out of cotton markets can also make prices unpredictable and volatile. Thus, making it difficult for producers to predict the direction of cotton prices. Speculative money could continue to push cotton prices higher. However, when speculative money leaves cotton markets, prices will fall sharply (possibly with a temporary correction below the price supported by global cotton supply and demand fundamentals).

Trade Uncertainty

In addition, another reason for the strong recovery of cotton prices since the pandemic is attributed to strong export demand, partially driven by the Phase One purchase by China in 2020 and 2021 (Figure 3). In the Phase One Trade Deal between U.S. and China, China agreed to purchase at least \$40 billion worth of agricultural products for each of the two years (2020 and 2021). However, China's purchase obligation under the Phase One Trade Deal only lasts until the end of 2021. There is uncertainty for future years of cotton purchase by China.

Figure 3. U.S. Cotton Export to China. Data includes cotton and cotton linters. Data Source: USDA FAS.

Georgia Situation

In Georgia, the planted acres declined to 1.17 million acres in 2021, 20 thousand acres lower than 2020, down from 1.4 million acres in 2019. Even though, with reduced planted acres, the weather conditions for 2021 favors cotton production in Georgia, with estimated 2.3 million bales of cotton produced in 2021. The average cotton yield in Georgia is 952 pounds per acre, which is the fourth-largest on record.

Comparison of Expected Net Returns

Table 3 below provides estimates of net returns per acre for corn, cotton, peanuts, and soybeans for 2022. This table is best used to compare net returns for row crops for planning purposes. Prices and costs can change and vary according to the practices of each individual farm. Comparing net returns for irrigated and non-irrigated production suggests that soybean may attract more irrigated acres and peanuts in non-irrigated acres in 2022.

2022 Price Outlook Summary

U.S. cotton acreage and production would be more likely to recover slightly for 2022, depending on the relative prices among competing crops during planting season in 2022. As this is being written, futures prices (December 22) for the 2022 crop are currently around 90 cents per pound. The optimistic likely price for 2022 is 90 to 100 cents per pound or better. The pessimistic likely price

for 2021 is 70 to 80 cents per pound. For planning and budgeting projections, a price of 80 to 90 cents per pound is suggested for 2022.

Table 3. Comparison of Projected 2022 Net Returns Per Acre, Irrigated Production

	Cotton	Peanuts	Corn	Soybeans
	<i>Irrigated Production</i>			
Expected Yield Per Acre	1200	4700	200	60
Expected Price	\$0.85	\$440	\$5.50	\$11.00
Gross Return Per Acre	\$1,020	\$1,034	\$1,100	\$660
Variable Costs Per Acre ¹	\$716	\$726	\$862	\$344
Net Return above Variable Costs Per	\$304	\$308	\$238	\$316
	<i>Non-Irrigated Production</i>			
Expected Yield Per Acre	750	3400	85	30
Expected Price	\$0.85	\$440	\$5.50	\$11.00
Gross Return Per Acre	\$638	\$748	\$468	\$330
Variable Costs Per Acre ¹	\$601	\$638	\$426	\$288
Net Return above Variable Costs Per	\$36	\$110	\$41	\$42

¹ Average of conventional and strip-till production. Excludes land rent. Due to extreme volatility in input markets, prices may change rapidly. You are encouraged to use the UGA Agricultural and Applied Economics Extension Row Crop Comparison Tool and enter your own prices to best estimate your 2022 cost of production. <https://agecon.uga.edu/extension/budgets.html>

FERTILIZATION

Lime

The official UGA recommendation or “target” pH (measured in water) for cotton is 6.0. However, a field with an average pH of 6.0 may very well have large areas measuring below this target pH. Recent precision soil sampling techniques have indicated that this happens frequently. Therefore, growers using standard soil sampling techniques (one composite sample per field) are encouraged to maintain their soil pH for cotton between 6.0 and 6.3. **Grid sampling (2.5 acre grids being most common) and variable rate liming is encouraged, especially where large areas of fields that have been traditionally sampled have been diagnosed with soil pH problems.** Liming to pH values above 6.3 may cause manganese deficiency problems in the Flatwoods soil region. However, this problem can be handled easily with applications of foliar Mn during the growing season. Liming to between 6.0 and 6.3 for all soil regions in Georgia is critical for proper uptake and utilization of nutrients that are essential for plant growth. Fertilizer use efficiency is also best in this range. In addition, toxic elements such as aluminum (Al) are kept unavailable when pH is above 5.5.

There are many factors that affect the soil pH reading obtained from soil testing. Possible reasons for seeing abrupt changes in soil pH include 1) sampling variability (spatial and depth), 2) rainfall amounts and 3) nitrogen fertilizer usage. Even so, changes of more than 0.5 in soil pH in one year should be considered suspect and call for resampling.

Another sampling variable (in addition to spatial and depth) is temporal variation. Soil pH can vary naturally over the course of a calendar year due to the salt concentration in the soil and how the pH

is measured. **Most private labs and University labs, with the exception of the UGA Soil testing Lab, measure soil pH in water (1:1 soil to water volume).** Since salts have a tendency to leach out of our sandy Coastal Plain soil in winter (January-March) this can lead to “false high” soil pHs. While this problem does not appear to be widespread, it does appear to be occurring more in recent years. Since January-March is a popular time frame to take soil samples in Georgia, if results from a soil sample show a field rising in pH compared to results taken the previous year, and especially if the rise in pH is more than 0.5 units and no lime was applied, then this result should be considered suspect. Since it will take time for the salts to re-accumulate and get an accurate measurement using the “water” method, either wait a few months to resample or have the sample run in dilute salt, the method currently used at the UGA Soil Testing Lab.

Dolomitic lime (that has 6 % or more Mg) is still a common liming material used on Georgia cotton and provides magnesium (Mg) as well as calcium (Ca) and a pH adjustment. The use of calcitic lime (less than 6% Mg) is becoming more popular in Georgia every year and may be used in cases where high soil Mg levels occur. If calcitic lime is used for consecutive years, soil test Mg levels should be tracked closely with soil testing. As soon as soil test Mg levels start to drop out of the high range into the medium range, the use of dolomitic lime should be resumed. The reason for this is that dolomitic lime is the most economical source of Mg fertilizer. In addition, a good liming program should supply all the Ca that a cotton plant needs for high yields and quality. Calcium deficiency in cotton is very rare, and the need for foliar Ca applications or small doses of supplemental Ca applied to soil should be considered unnecessary.

Phosphorous and Potassium

Phosphorous (P) and potassium (K) levels in soil should be maintained in the upper medium range as determined by soil testing. All of the P requirements should be applied preplant since it is relatively immobile in soil and is important to seedling growth. All of the K requirements should also be applied preplant on all soil types including Piedmont, Coastal Plain, and Deep Sand soils. Widespread K uptake and deficiency problems continue to occur in Georgia cotton every year.). This problem is also made evident by weak areas in the fields (usually in sandy washed out areas) and the presence of certain leafspots. Cercospora, Alternaria and Stemphylium leafspot have all been linked to potassium deficiency. These leafspot diseases are considered secondary to potassium deficiency and if potassium deficiency is avoided then these leafspots should not be an issue. Corynespora leafspot, however, does not appear to be linked to potassium deficiency.

Split applications of K, especially half the recommended rate at planting and half at sidedress, have also not proven to be effective on Tifton type soils. In fact, in some cases this approach may lead to potassium deficiency before sidedress applications are made. Recent field trials conducted in Georgia have focused on additional soil-applied K during N sidedressing versus foliar K applications during peak bloom (first 4 weeks of bloom). Preliminary results from studies conducted on Coastal Plain soils indicate that foliar K may be more effective than sidedress K in improving yields. Research on Deep Sands is still needed to determine which approach is more effective. **Currently, foliar K applications should automatically be considered on deep sands (more than 18 inches to subsoil clay), low K soils, high Mg soils, high-yielding conditions, short season varieties and especially, where severe K deficiencies and leafspot have been observed in the past.** Two foliar applications of 5-10 lbs/K₂O in each application during early bloom (first thru 4th week of bloom) should be considered in these situations.

Because current cotton varieties are relatively fast fruiting and early in maturity, this makes them more susceptible to K deficiency. In most situations, **the best strategy to avoid K deficiency is to 1)**

soil test, 2) apply the recommended K fertilizer at planting, and 3) consider foliar feeding K during peak bloom.

Currently, there are a number of commercially available fertilizer additives that are designed to improve the uptake efficiency of P and K fertilizers. Research results with Georgia cotton showing consistent advantages to these materials have not been seen at this time and their widespread adoption is not recommended.

Also, the practice of applying P and K fertilizer for Georgia cotton in the fall (“fall fertilization”) is not recommended due to the chance of leaching K below the root zone on deep sands with adequate winter rainfall. Nitrogen is highly mobile and should not be applied in the Fall. Fall fertilization of P only would be acceptable however there are very few “P only” fertilizer materials (that do not contain some N and/or K) presently available to Georgia cotton growers.

Nitrogen Management

Nitrogen is probably the most important fertilizer used on cotton, yet it is the most difficult to manage. Low N rates can reduce yield and quality while excessive N rates can cause rank growth, boll rot, delayed maturity, difficult defoliation, and poor quality and yield. Total N rates for cotton should be based on soil type, previous crop, growth history, and yield potential. Base N rates recommended by the UGA Soil Testing Lab according to yield goals are listed next.

Yield Goal (lb lint/A)	Recommended N Rate (lb N/A)
750	60
1000	75
1250	90
1500	105

These N rates should then be adjusted according to other factors. For example:

Increase N rate by 25% if:

- Deep sandy soil
- Cotton following cotton
- History of inadequate stalk growth

Decrease N rate by 25% if:

- Cotton following peanuts or soybeans
- Cotton following good stands of winter legumes such as clover or vetch
- History of rank or excessive vegetative growth

Yield goals should always be realistic, preferably based on past production records. For N rates above 120 lb/A, cotton should be highly managed in terms of insect control, plant height, and boron fertilization. Total N rates above 120 lb/A should only be needed on deep sands or in special cases of history of inadequate stalk growth or where excessive leaching has occurred. The N rates for 1250 and 1500 lb lint/A yield goals assume irrigation.

The total N rate should always be applied in split applications. Apply 1/4 to 1/3 of the recommended N at planting and the remainder at sidedress. The preplant or at planting N application is critical for getting the crop off to a good start and ensuring adequate N nutrition prior to side-dressing. **Sidedress N between first square and first bloom** depending on growth and color (toward first square if slow growing and pale green, toward first bloom if rapid growth and dark green). A portion of the sidedress

N can also be applied as foliar treatments or through irrigation systems. **No N should be soil-applied (either top dressed or through the pivot) after the 3rd week of bloom.** Studies have shown that uptake of soil-applied N from by cotton roots is basically ineffective after this critical point.

There are a number of sidedress nitrogen fertilizer materials that can be used on cotton including liquid UAN solutions, ammonium nitrate and urea. UAN solutions are made up of urea and ammonium nitrate and often contain sulfur (e.g. 28-0-0-5). Ammonium nitrate is losing favor as a sidedress N source for cotton due to higher cost and burn potential. Urea is considered an alternative to ammonium nitrate but is known to be prone to volatilization losses. Volatilization losses can be minimized however by irrigating after a urea application or by use of a urease inhibitor that contains the active ingredient NPBT. Another popular liquid sidedress N source for Georgia cotton is “19 %” or 18-0-0-3(S). These sources are derived from a by-product of the Attapulgitic clay mining industry in southwest Georgia and are basically “liquid ammonium nitrate and sodium nitrate” (approximately 60 % nitrate and 40 % ammonium with no urea). Replicated, small plot research trials conducted between 2010 and 2012 indicated that 18-0-0-3(S) is comparable to 28-0-0-5(S) in terms of producing cotton yield. For foliar feeding N, feed grade urea is still the product of choice in terms of performance and cost. Controlled release nitrogen foliar products are also available but usually contain potassium and boron and are less concentrated in N.

Sulfur

The official UGA fertilizer recommendation for sulfur is 10 lb/A. Sulfur can be applied either with preplant fertilizer or with sidedress N materials such as 28-0-0-5 or ammonium sulfate. Sulfur fertilization is most important on sandy, low organic matter Coastal Plain soils. With less S input from cleaned (“scrubbed”) power plant smokestack emissions and the recent trend toward high-analysis (S-free) fertilizers, including S in a cotton fertilizer program is currently very critical. Adequate S fertilization is also important where higher rates of fertilizer N are used. Since S deficiency symptoms are similar to N deficiency (yellowing) and the N:S ratio in plant tissue is a good indicator of S nutrition, a plant tissue sample greatly aids in diagnosis when low S is suspected.

Boron

Boron (B) is an essential micronutrient that is important to flowering, pollination, and fruiting of the cotton plant. The standard **UGA recommendation of 0.5 lb B/A**, applied in two 0.25 lb/A foliar applications between first square and first bloom, fulfills the base requirement for B. Single applications of 0.5 lb B/A can be used but include a greater risk of foliar burn. Foliar applications above the base recommendation of 0.5 lb B/A and up to 2 lb B/A (applied in increments of no greater than 0.5 lb B/A per application) may help move nitrogen and carbohydrates from leaves into developing fruit. Cumulative applications totaling above 2 lb B/A, however, may reduce yields and quality. The need for additional B above the 0.5 lb/A rate is best determined by tissue or petiole testing. Since B leaches readily through sandy soils, foliar applications have always been considered the most effective and efficient application method. However, on a typical Coastal Plain soil like the Tifton series, with normal rainfall and irrigation, preplant, starter, and sidedress soil applications are also be considered effective. If no B is included in preplant, starter, or sidedress soil-applied fertilizer applications, is foliar B alone (with no insecticide or growth regulator) worth the trip? Yes, especially on sandier soils and with irrigation or adequate rainfall.

Numerous B fertilizer materials are currently available. Most are either derived from boric acid or sodium borate and can be either in the liquid or wettable powder form. There are many “additives” used with these base B materials such as nitrogen and complexing agents designed to improve

efficiency of uptake. However, extensive field testing over recent years has proven that all of the B fertilizers currently on the market are equally effective in terms of plant nutrition. Therefore, choice of B fertilizers should be made on price per pound of B.

In addition, at least one boron fertilizer currently sold in Georgia is recommended at application rates well below the recommended 0.5 lb B/A rate -- in fact the labeled rate only provides 0.025 lb B/A !. **As far as fulfilling the base recommendation for B, any boron fertilizer recommended at a rate that does not provide at least 0.25 lb B/A should be considered uneconomical!**

Figure 4. Relationship between pH and manganese availability. Maintain soil test manganese levels above the line to help avoid manganese deficiency. Source: Soil Test Handbook for Georgia.

Manganese and Zinc

Manganese (Mn) and zinc (Zn) are two essential micronutrients that are routinely measured in soil testing at UGA and can sometimes be deficient in cotton. Both Mn and Zn are less available for plant uptake at higher soil pH. Therefore, soil test results should be examined closely for the combination of low levels of Mn or Zn and high soil pH. In order to minimize the chance of Mn deficiency on cotton, minimum levels of soil test manganese should be maintained with varying pH levels as shown in Figure 4.

Notice on the graph, that if soil pH is at the recommended target of 6.0, soil test level of Mn should be at least 5 lb/A. At soil pH of 6.5 the soil test level of Mn should be at least 11 lb/A.

Even when the soil test level of Mn falls below the recommended level for a given pH, the result is not an automatic recommendation to apply Mn fertilizer. Instead, the crop should be monitored using tissue testing between first square and first bloom and foliar Mn can be applied if a deficiency is confirmed. Small amounts of Mn can also be added to starter fertilizer applications. Be sure to read and apply Mn and other micronutrients starter packages according to label to avoid burn and stand loss.

Large amounts of soil applied Mn (above 5 lb/A) are not considered to be economical. Therefore, in situations where soil test levels of Mn need to be built up, do so slowly and monitor the crop for deficiency using tissue testing. In essence, if a grower likes to maintain soil pH near the UGA target pH of 6.0, then soil test Mn should be built to and maintained around 5 lb Mn/A. If the grower likes to maintain soil pH at a higher level, say around 6.5, then the soil test level of Mn needs to be built to and maintained around 11 lb/A.

Cotton growers in the Flatwoods soil region are cautioned not to maintain soil pH above 6.3 to minimize the chance of Mn deficiency (peanuts and soybeans are also susceptible to Mn deficiency at this pH on these soils). If soil pH is maintained above 6.3 on these soils, tissue testing is recommended regardless of soil test Mn levels in order to avoid deficiencies. If a deficiency is detected in this situation, it can be corrected by foliar feeding Mn.

Soil test levels of zinc should be maintained between 2 and 8 lb/A (Mehlich 1 extractant). Unlike Mn, if soil test Zn falls below this range, it is considered low and an application of zinc fertilizer will be

recommended. The recommended Zn fertilizer can be applied with broadcast preplant fertilizer or more efficiently, with a starter fertilizer application. In the event that no zinc is applied to the soil even though recommended by soil testing, a foliar application of zinc can be made. Tissue testing in both cases, whether Zn was applied to soil or applied foliar, is recommended. The tissue sample should be taken between first square and first bloom. Tissue sampling at first square is better than at first bloom in order to correct the deficiency before the crop experiences any possible reduction in yield.

Deficiencies of the other essential micronutrients including copper, iron, chlorine, and molybdenum in Georgia cotton are extremely rare.

Petiole and Tissue Testing

The University of Georgia used to offer a 10-week petiole testing program for monitoring the N and K status and for making N, K, and B foliar applications. Leaf stems (petioles) were sampled weekly from the same field starting the week before first bloom and analyzed for N, P, and K. Depending on the relationship between N and P, along with other information such as soil moisture and fruit load, foliar N and/or B was recommended. Potassium levels were also monitored and in the case of K deficiency, soil-applied or foliar K applications will be recommended. A valuable feature of petiole testing programs was that weekly sampling tracked nutrient level trends and allowed the detection of deficiencies or excesses up to 2 weeks in advance. Due to labor and time costs, Georgia cotton growers were not utilizing the 10-week petiole testing program at UGA and therefore it has been discontinued.

Petiole testing for troubleshooting is still available and can still be a valuable tool for making in-season correction of certain nutritional problems (namely N and K). “Spot checking” with petiole sampling can be done as many weeks during the fruiting period as desired. Simply sample the petioles and send them to the UGSA lab for analysis and a recommendation of where the typical nitrate and K levels should be for that week of bloom.

Tissue testing (the leaf blade without the petiole) is also available through the University of Georgia lab and can be especially helpful to detect deficiencies of nutrients not included in petiole testing. Tissue testing is used differently than petiole testing in that it is more important for correcting nutritional problems prior to bloom and can detect different nutritional problems such as with magnesium, sulfur manganese and zinc. The most common growth stage when cotton leaf tissue is sampled is early bloom, the same time as the first petiole sampling. However, tissue sampling can be helpful earlier during the “vegetative” stage to detect and correct early nutrient problems. Tissue sampling can also be used any time during the growing season when trouble shooting if samples are taken from both normal (“good”) and affected (“bad”) areas of a field.

Since petiole and tissue samples tell different things, it is recommended that both are taken during troubleshooting (especially when past the first bloom stage). For example, petiole samples appear to be a better indicator for N and K deficiency than tissue samples when troubleshooting, but tissue samples are useful for detecting S deficiency (based on the N:S ratio) and micronutrient deficiencies. Also, petiole samples analyzed as tissue samples and vice versa will result in useless information. For example, measuring the nitrate level in a tissue sample or total N in a petiole cannot be interpreted since no data are available for these measurements.

Private labs in the state also offer petiole testing programs and tissue testing services. In recent years, reduced-frequency petiole sampling programs (3 or 6 weeks) and combination packages (petiole and

tissue tests) have been offered by private labs. These programs (for example, sampling at the vegetative, early bloom, and late bloom stages) can be attractive due to less sampling and the opportunity to automatically check on secondary and micronutrients with an early tissue test. Timing is even more important with the less-frequently sampled programs since results are based on critical stages of nutrient demand by the cotton plant.

Consistent soil moisture increases the reliability of petiole testing results. Representative samples are more critical for petiole testing than with soil testing. Growers and scouts are urged to closely follow sampling instructions and to provide exact information requested for each sample. Apart from good sampling techniques and consistent soil moisture, petiole results can be unreliable and confusing.

Foliar Fertilization

Foliar fertilization of cotton should be used to supplement a good soil-applied fertilizer program. The most likely nutrients needed for foliar applications are N, B, and K. Foliar N applications can be made as part of an overall N management strategy or as determined by petiole testing. Feed grade urea is the most reliable, economical, and proven foliar N material. The standard recommendation is for 4.5 lb N/A as urea in 5 gal or more of water (5gal/A assumes aerial application). Both liquid (23 % N) and granular urea (46 % N dissolved into water) can be used. Applying all the recommended K to soil preplant or at-planting should provide sufficient K for Georgia cotton in most cases. Potassium nitrate is the most common material used for foliar K applications. The standard recommendation is for 4.4 lb K₂O /A in 5 gal or more of water. Again, 5 gal/A assumes aerial application and both liquid and granular KNO₃ can be used. If potassium nitrate is not available, there are other foliar K fertilizers available (for example, liquid 5-0-20) that can also be used to foliar feed K. However, many of these materials do not contain as much K and cannot be applied at rates comparable to potassium nitrate without causing significant leaf burn.

Based on field research trials, foliar fertilization is most effective when applied during peak bloom or the first 4 weeks of bloom. Foliar feeding during the 5th – 7th week of bloom may or may not be effective depending on the particular cotton variety grown. **How late is too late to foliar feed cotton? Once you pass the 8th week of bloom, it is too late and no foliar feeding is recommended.**

Starter Fertilizers

Although starter fertilizers do not consistently increase cotton yields, they are an effective way of providing early N and P as part of an overall fertility program. Yield responses have been most consistent where soil P levels are low or when planting in cool, wet soils. The use of starter fertilizer is strongly encouraged for conservation tillage systems and in high yield situations. Even though yield responses may not be realized, other advantages include the development of strong root systems and the encouragement of early rapid growth for weed control with directed herbicide sprays.

Ten gal/A of 10-34-0 is probably the most common starter fertilizer treatment used on Georgia cotton. Nitrogen solutions (with or without S) and complete (N-P-K with micronutrients) dry fertilizer materials can also give good results. Recent research conducted in Georgia showed that the choice of starter fertilizer should depend on soil type and conditions. For example, on “red dirt” such as the Greenville series that has a high affinity for P, P-containing materials such as 10-34-0 should be used. On “stiffer” Coastal Plain soils such as the Tifton series that have medium to high soil test P, N-only materials such as 32 % N liquid can be used. On sandy Coastal Plain soils with histories of S problems, N+S materials such as 28-0-0-5S should be considered. An economic evaluation of this same research showed that in 23 out of 30 comparisons, starter fertilizer gave greater economic returns compared to

the untreated check. Adding liquid micronutrient packages to liquid starter materials is also gaining in popularity. This may be a good way of providing recommended B, Zn, and Mn in an overall fertilization program.

The recommended placement for any starter fertilizer is 2 inches below and 2 inches to the side of the row (also referred to as “2-by-2”). **No starter fertilizer materials should be placed in direct contact with the seed in the furrow.** “Dribbling” liquid starter fertilizers on the soil surface, 2 inches to the side of the furrow (to avoid possible leaching into the seed zone) has proven effective on sandy soils but does not work on “stiffer” soils. **Avoid using starter fertilizer rates greater than 15 lb N/A**, even in the 2-by-2 placement, in order to reduce the risk of “starter burn.” Under certain conditions - namely dry, sandy soil -- even 15 lb N/A can burn cotton seedlings if not placed properly.

Starter fertilizers can also be applied in conjunction with herbicide applications by spraying narrow bands (3 to 4 inches) directly over the row behind the press wheel. Mixing liquids containing both N and P with preemergence herbicides can result in clogging of spray nozzles and can decrease the fertilizer effect (or benefit) by spreading the material in a wider band. However, this may supply some needed N when no other preplant N has been applied. Rates should not exceed 20 lb N/A when this method is used.

Poultry Litter

Managed properly, poultry litter (manure mixed with wood shavings) can be a valuable source of plant nutrients for Georgia cotton. The fertilizer value of poultry litter varies depending on a number of factors including moisture, temperature, feed rations, number of batches before clean-out, storage, and handling. However, broiler litter has an approximate analysis equivalent to 3-3-2 (%N – % P₂O – % K₂O). Based on this average, one ton of broiler litter contains 60 lb/A of N, 60 lb/A of P₂O and 40 lb/A of K₂O. Based on record-high fertilizer prices for N, P, and K in 2008, poultry litter was valued as high as \$90/ton. By using current fertilizer prices, producers may calculate the value of a ton of poultry litter. This value would normally be calculated by the N, P and K in the litter, if soil test P is high and no P is called the value of litter would be lower. Also to consider it that this value also does account for the lower availability of N compared to commercial fertilizer (60 % compared to 100 %). As the price of N, P and K varies, this value needs to be continuously adjusted. Also, due to variability, it is recommended that litter be analyzed for nutrients by a reputable laboratory before application rates are determined.

Poultry litter on cotton should be managed to provide preplant P and K and a portion of the total N requirement. The remainder of the N requirement should be applied as commercial fertilizer at sidedressing. For example, 2 tons/A of poultry litter preplant incorporated followed by 30 to 60 lb/A of sidedress N (depending on soil type) is a good, basic strategy. This approach should avoid unnecessary P buildup and should not cause rank growth, boll rot, or defoliation problems typically associated with excess N. In addition, the availability of N from poultry litter, because it is an organic material, is less predictable than from commercial fertilizer. Therefore, side-dressing with commercial fertilizer N assures adequate N availability when the crop needs it the most. The amount and timing of N released from litter depends on a number of factors, including soil pH, temperature, sand content, and available moisture. As a rule of thumb, 60% (or 36 lb N/ton of litter) is made available for crop uptake during the season if the manure is incorporated into the soil prior to planting. Most of the remaining N in the litter (about 40%) is either lost or “tied up” during the growing season and should not be considered for carryover to the next crop. Since N availability from poultry litter can be highly variable, petiole testing is strongly recommended. Build up of soil P and Zn are long-

term concerns for using poultry litter as fertilizer. However, at the 2 ton/A rate, there are no short-term concerns for poultry litter use in cotton.

The only situation where poultry litter rates above 2 ton/A should be considered is where problems with “black root” are suspected. Black root is isolated to poorly-drained Flatwoods soils and has not been that prevalent in recent years. Rates of 3 to 4 tons of poultry litter per acre have been shown to alleviate this problem dramatically. However, at the 4 ton/A rate excess soil P will build rapidly. Therefore, this solution should only be considered a short-term fix and not a long-term strategy.

How early can I apply chicken litter for cotton? In general, it is best to apply any base fertilizer nutrient (inorganic/commercial or organic like chicken litter) close to when a plant needs it, typically 2- 3 weeks before planting. Therefore, ideally, chicken litter would not be applied until around April 1 for May planted cotton. Timing of acquiring litter and availability of labor tempts growers to apply litter as early as December and January. This is not recommended since most of the N and some of the K can be lost before the cotton crop will ever be established (depending on soil type and rainfall). In addition, if a cover crop is grown, the cover crop will take up the nutrients from the litter and greatly decrease the availability to the cotton crop. **If at all possible, delay applying chicken litter for cotton until at least February 1.**

Other By-Products

As landfill costs and regulations increase, more by-products are becoming available for land application on row crops such as cotton. These by-products are not only from the agricultural sector (such as poultry litter), but also from municipalities and industry. Examples include gin trash, mushroom compost, yard waste, biosolids, dairy manure, composts, fly ash, and wood ash. These materials may have some value as fertilizers, soil amendments, or liming materials. They may be free or available at very low cost. However, great caution is needed when considering the use of any by-product to ensure it can be used, safely, effectively, and economically.

Before considering the use of any by-product material on cotton, investigate the properties of the material. Find out what value it has (as either lime, fertilizer, soil amendment, or a combination), if it is safe (for example, low in heavy metal content and free of any toxins), how much it costs, and if it will handle and spread easily. Fortunately, any by-product material to be used as a fertilizer, lime, or soil amendment in Georgia must first be approved by the Department of Agriculture. Since by-products are unique, they should be investigated on a case-by-case basis.

WEED MANAGEMENT IN COTTON

Effective weed management is one of many critical components of successful cotton production. Because cotton does not compete well with weeds, especially early in the season, a given number of weeds will reduce cotton yield more than corn or soybean yield (Fig 5). Weeds also may interfere more with harvesting of cotton and can reduce lint quality because of trash or stain. The most problematic pest infesting cotton production in Georgia is Palmer amaranth (Fig 6). Interestingly, 6 of the top 10 most challenging pests for growers were weeds.

Figure 5. Irrigated Cotton Seed Yield vs. Glyphosate-Resistant Palmer Amaranth Density.

Figure 6. List Your Most Challenging Pests

Response	Times provided	Points by ranking*
Palmer amaranth (pigweed)	1773	4983
Morningglory	238	572
White flies	155	318
Dayflower (spiderwort)	131	254
Sicklepod	113	223
Stink bug	105	226
White mold	61	95
Nutsedge	48	82
Nematodes	47	94
Annual grasses	41	74

*Points were determined by giving 3 points for 1st choice of importance, 2 points for 2nd choice, and 1 point for 3rd choice. All locations - 1737 growers participated

CROP ROTATION

Crop rotation aids in the management of nematodes and diseases and is often critical in delaying herbicide resistance and improving weed control. It also enhances the opportunity for improved diversity in management tactics; including using herbicides with different modes of action on the same field across years. By rotating cotton with other crops and selecting an herbicide program for the rotational crop that effectively controls the weeds that are difficult to control in cotton, one can reduce the impact of problem weeds.

One must carefully select herbicides used in the crop preceding cotton making certain those products do not carryover and harm the cotton crop. This information can be found on herbicide labels. Many of the commonly used herbicides in other crops do not carry over to cotton. However, labels for products listed below contain significant rotational restrictions.

Active ingredient	Examples of a few of the products containing the active ingredient
diclosulam	Strongarm
imazapic	Cadre, Impose, Nufarm Imazapic
imazethapyr	Authority Assist, Extreme, Lightning, Matador, Optill, Pursuit, Thunder, Thunder Master
sulfentrazone	Authority Assist, Authority First, Authority Maxx, Authority MTZ, Authority XL, Blanket, Broadaxe, Sonic, Spartan, Spartan Charge, Spartan Elite, Sulfentrazone, Zeus

Similarly, cotton herbicides such as Cotoran, diuron, Envoke, fomesafen (Reflex, other), and Staple have significant rotational restrictions to some commonly grown crops. Thus, one needs to carefully consider which herbicides are to be applied in cotton avoiding damage to the following crop.

TILLAGE

Deep Turning:

This practice can assist in the management of certain insects and diseases while improving the control of many weed species, especially small seeded weeds. For success, it is critical to understand the biology of the weedy pest that one is attempting to manage. For example, research notes Palmer amaranth rarely emerges from depths below 4 inches (Fig. 7). Thus, seeds buried to a depth of at least 4 inches will not emerge *improving weed control and resistance management* (Fig. 8). It is important to note that the lifespan of the seed in question is critical in determining the interval needed before implementing deep turning again.

Figure 7. Influence of burial depth on Palmer amaranth emergence

Keeley et al. (1987) reported 36-44% emergence at 0-1", 7% at 2", and 2% at 3".

Figure 8. Number of Palmer amaranth plants during early season. Macon Co., GA 2008.

Cultivation

Most cultivation disappeared with the adoption of Roundup Ready Technology in the late 1990's until glyphosate-resistant Palmer amaranth forced some growers back to plowing from 2005 through 2015. The adoption of technologies tolerant to glufosinate (Liberty, etc.) and the auxin herbicides (dicamba and 2,4-D) have allowed growers to once again eliminate cultivation for all practical purposes.

Cultivation can be used to effectively manage small weeds between cotton rows. Cultivate prior to most weeds reaching 3 inches and tropical spiderwort reaching 2 inches. Also, if possible, avoid rainfall or irrigation for at least 48 hours after cultivating. This practice will likely destroy any residual herbicides present; thus, the application of a residual herbicide immediately after the last cultivation for the season may prove beneficial. *Cultivation can be an effective component of a resistance management strategy.*

In addition to controlling weeds, cultivation may improve early-season cotton growth in tight or crusted soils. On most soils, however, cultivation is usually of no value beyond weed control. For growers who are able to eliminate cultivation, this often reduces the following: equipment and labor demands, subsequent weed flushes, destruction of residual herbicide activity, moisture loss, and root damage associated with the practice.

COVER CROPS

Unlike never before, herbicide resistance threatens the sustainability of our family farms. Cover crops, if managed properly, have the potential to greatly reduce herbicide selection pressure for many weeds thereby extending the life of herbicides. Research shows an effectively grown grain cover crop that is rolled prior to planting can reduce Palmer amaranth emergence 65 to 90%. Control is not a result of allopathy but rather from the impact of blocking the sunlight from reaching the soil and/or simply

serving a mulching effect. In general, the greater the level of biomass and the greater the length of stability of that biomass then the greater weed suppression that will be observed. In nearly all fields infested with Palmer, an herbicide program will be needed in conjunction with the cover crop for long-term success. For detailed information on the rolled rye system for cotton production watch the following DVD: https://www.youtube.com/watch?v=F0VTHsRO_0Q&feature=youtu.be

PLANNING A HERBICIDE PROGRAM

Before selecting herbicides, one should know what weeds are present or are expected to appear, the soil characteristics (such as soil organic matter and texture), the capabilities and limitations of the various herbicides, the weeds controlled by these herbicides, and how to best apply them. Application rates for herbicides with residual activity depend on soil texture, organic matter content, and irrigation program. Failure to adjust application rates for soil characteristics and irrigation scheduling may result in poor weed control or severe crop injury. Herbicide rates for control of emerged weeds are usually determined by weed size.

Weed Mapping. The first step for a successful weed management program is to identify the problem which is best accomplished by weed mapping. Survey fields each fall documenting species and population levels present on a field map. Species present in the fall will likely be the predominant problems during the following year. Knowing which species are likely to occur will allow one to develop a more effective herbicide program. Additionally, by referring to weed maps over a period of two or three years, one can detect shifts in the weed populations and make adjustments in the herbicide program to deal with changes that occur. Proper weed identification is critical as different weed species respond differently to various herbicides.

In-Season Monitoring. During the first 6 weeks after planting, check fields every 3- to 5-days to determine the need for postemergence herbicides or cultivation. From the sixth week through canopy closure, check fields weekly to evaluate the success of the weed management program and to determine the need for additional control measures. If weeds are controlled for the first ten weeks, any later emerging weeds will seldom become problems for harvest but could increase the number of seed being added to the seedbank.

HERBICIDE RESISTANCE MANAGEMENT

Herbicide resistance in weeds is not a new problem. However, the threat posed by herbicide resistance has been elevated in recent years. Palmer amaranth resistant to glyphosate (Roundup), ALS-herbicides (Staple, Envoke, Cadre), DNA-herbicides (Treflan, Prowl), and/or atrazine have been confirmed to infest numerous Georgia agronomic producing counties. In 2020, Palmer amaranth resistance to POST applied PPO herbicides (Reflex, Ultra Blazer, and Cobra) was confirmed in Georgia (Fig 9) and during 2022 Palmer amaranth resistant to the residual activity of Reflex and Valor was confirmed. Also of importance, common ragweed, goosegrass, horseweed, johnsongrass, and ryegrass resistant to Roundup are scattered across the country.

Figure 9. Palmer amaranth response to PPO herbicides POST.

In the past, growers with herbicide-resistant weeds were fortunate to have new herbicides (specifically, new mechanisms of action) come into the marketplace before the problem became

overwhelming. That is no longer the case; thus, it is imperative that growers take herbicide resistance management very seriously and maintain usefulness of current products and technologies.

What Causes Resistance? Herbicide resistance is the inherited ability of a biotype of a weed to survive and reproduce following exposure to a dose of herbicide normally lethal to the wild type. Herbicides do not cause resistance. Rather, herbicides select for resistance that is naturally occurring in the population. Greater reliance on a particular herbicide, or group of herbicides, with the same mode of action puts greater selection pressure on any resistant individuals that may be in the population. Additionally, applying sub-lethal herbicide rates or making untimely herbicide applications can foster the development of resistance.

Resistance Management Strategies. There are two prerequisites for resistance. First, one or more individuals possessing genes conferring resistance must be present in the population. Second, selection pressure resulting from use of an herbicide to which these rare individuals are resistant must be exerted on the population. Growers have no way to know if a few plants carrying resistance are present on their farm. Hence, the only way to prevent a buildup of resistant plants is to utilize resistance management strategies.

Nearly all of Georgia's cotton is tolerant to Roundup (glyphosate); corn and soybean acres are similar. In the past, growers relied almost exclusively on Roundup for weed control. Extensive reliance on a single mode of action (the mechanism by which the herbicide kills susceptible plants) over that much acreage puts tremendous selection pressure on resistant weeds present in the population and this is one of the reasons glyphosate-resistant Palmer amaranth currently dominates the landscape.

It is absolutely essential that herbicide programs 1) are integrated with other cultural control practices (hand-weeding, tillage, cover crops, crop rotation, etc.), 2) are diverse in herbicide modes of action, and 3) are implemented in a timely manner maximizing activity thereby reducing herbicide selection for resistant weeds. Incorporating diversity in herbicide modes of action into a management program can be achieved by using soil-applied residual herbicides at planting and throughout the season, tank-mixing herbicides, and using conventional chemistry such as diuron as a layby directed treatment.

ON-TARGET PESTICIDE APPLICATIONS ARE CRITICAL FOR SUSTAINABILITY

Science is clear that pesticides are currently essential for U.S. farmer's to be able to feed and clothe the world. However, it is critical and will become even more important that pesticides are used judiciously and carefully to protect the user, the consumer, and the environment. Several of the greatest regulatory challenges facing family farms today include the following: 1) the endangered species act, 2) protecting pollinators, 3) pesticide resistance management and 4) pesticide drift. The most important approach to overcome each of these challenges is to ensure pesticide applications are made on-target, thereby mitigating any off-target exposure, and that they are applied within an integrated and diversified management approach. A joint partnership between The University of Georgia and The Georgia Department of Agriculture called Using Pesticides Wisely (UPW) has been developed to provide the latest science helping applicators make the best decisions possible when using pesticides.

MANAGING COMMON/TROUBLESOME WEEDS BEFORE PLANTING

Note: Check herbicide planting intervals restrictions before use.

Cover crops can be extremely effective reducing emergence of some weeds, especially Palmer amaranth, but some cover crops require a significant effort to kill. Small grains can usually be

controlled easily with Roundup; although the herbicide does not perform well during cold conditions and grains (especially wheat) are usually more tolerant at the jointing through boot stages of growth. Additionally once grains have mature seed, paraquat is very effective. *Of great importance, using ryegrass as a cover crop that is too be controlled with herbicides is strongly discouraged because of rapid resistance development.* For clover, dicamba and glufosinate (Liberty) mixtures are very effective. Roundup + dicamba or 2,4-D are very good options for vetch.

Broadleaf cover crops should be killed at least 10 days prior to planting; data thus far notes grass cover crops may be killed closer to planting but soil moisture depletion could be severe. Killing cover crops or weeds prior to planting will avoid soil moisture depletion, allow the soil to warm quicker, reduce cutworm or other insect issues, and allow additional burndown herbicides if needed. Heavy residue from a cover crop will help suppress most weeds, but growers should consider their equipment capabilities for strip-tilling and planting into residue in deciding when to terminate a cover crop. For growers planting into weeds, burndown should occur a minimum of 14 days before planting. Burndown herbicides are outlined in the “cotton weed control” appendix.

Cutleaf eveningprimrose and wild radish have traditionally been troublesome weeds to manage in reduced-till fields. The most effective and economical option for controlling primrose and radish is an application of 2,4-D alone or mixed with any Roundup mixture (such as Roundup + Valor) at least 30 days before planting. For primrose, 2,4-D at 12 oz/A of a 3.8 lb/gal formulation mixed with Roundup is sufficient and would reduce the interval between application and planting non-Enlist cotton cultivars; however, rates of 1.0 to 1.5 pt/A are needed for wild radish. Dicamba will also control primrose when mixed with Roundup; dicamba is not very effective on wild radish.

For growers who do not want to put 2,4-D or dicamba in their sprayers, Liberty or a combination of Roundup plus Valor are options to provide fair (70 to 80%) control of pre-blooming primrose; full blooming primrose will be controlled about 15% better. For wild radish, regardless of growth stage, Roundup mixtures containing Harmony Extra are effective. After radish is in full bloom, Roundup + Valor will provide 75 to 90% control. Additionally, once primrose and radish are in full bloom, good to excellent control should be achieved with paraquat plus Direx.

Glyphosate-Resistant Horseweed or Fleabane: Glyphosate-resistant horseweed (also called marehail) and fleabane are common as seed are easily spread by wind and equipment. These weeds germinate primarily in the fall, but additional plants may emerge in late spring. Plants emerging in the fall will be in a rosette stage and large enough for easy identification by early winter.

An early preplant burndown program is encouraged. Glyphosate-resistant horseweed and fleabane can be controlled by tank mixes of glyphosate plus 0.95 lb a.e./A of 2,4-D (2 pt/A of 3.8 lb a.e./gal formulation) or 0.5 lb a.e./A of dicamba (Engenia 12.8 fl oz or XtendiMax 22 fl oz). The addition of flumioxazin (Valor, others) in Roundup + 2,4-D or dicamba mixtures is suggested to provide residual control of these and other troublesome weeds. Mixtures with dicamba may perform more consistently than 2,4-D mixtures, although 2,4-D has typically worked well. Application in February (South GA) and March (North GA) is recommended. Control failures are usually related to later applications when the weed is too large.

Cotoran applied preemergence is a good option to control late-emerging horseweed; paraquat should be included with the Cotoran to kill emerged weeds.

In emerged cotton, several options do exist to control horseweed or fleabane. Enlist One plus Liberty or Roundup, Roundup plus Engenia or XtendiMax, or Tavium are effective options in their appropriate varieties. Liberty can also be used to manage horseweed if applied when daytime temperatures exceed 85 F; although less effective than 2,4-D or dicamba mixtures.

Palmer amaranth is by far the most problematic weed of cotton and it is essential that no Palmer amaranth be emerged at planting. Herbicides, cover crops, and tillage are options to achieve this goal.

For conservation tillage, the use of Valor and/or Direx preplant is critical. Valor is the most effective residual herbicide while Direx plus paraquat offers the most effective control of emerged plants (Table 4). Neither 2,4-D nor dicamba are that effective in controlling Palmer with a single application; especially when compared to Valor (before Palmer emerges) or paraquat + Direx once it has emerged. Make certain to follow the correct plant back interval (Table 5).

Table 4. The most effective options to eliminate emerged Palmer amaranth before planting.

CONSERVATION TILLAGE – STRIP TILL		
Option 1 Valor with glyphosate or paraquat <i>(Palmer < 1" and 7 or more d before planting)</i>	Option 2 Valor + Direx + paraquat <i>(Palmer ≤ 5" and 7 or more d before planting)</i>	Option 3 Direx + paraquat <i>(Palmer ≤ 5" and less than 10 d before planting)</i>

Table 5. Plant back intervals for Valor or Direx applied at burndown.

Herbicide	Time Interval Before Planting	Special Comments
Valor	<p>In strip-till, where the strip till rig (including ripper shank) is run after application and before planting.</p> <p>1) > 30% ground cover = 7 days 2) 10-30% ground cover = 14 days plus 0.5" rain/irrigation 3) <10% ground cover = 21 days plus 1.0" rain/irrigation</p> <p>In no-tillage production or when the strip is implemented prior to application. Valor plant-back interval should be 28 days. Additionally, 0.5" (>10% ground cover) or 1" (<10% ground cover) rainfall/irrigation is needed.</p>	<p>Do not exceed 2 oz/A if planting within 30 days.</p> <p><i>If applying Reflex (or generic PRE), add an additional 7 days to no-till planting intervals.</i></p>
Direx	<p><u>no till</u>: 10 d</p> <p><u>strip till</u> after application and before planting: 0 d</p>	<p>Do not exceed 1 qt/A, see label for rate on your soil.</p>

For conventional tillage production, tillage alone can be effective but the single most effective program would be a split Reflex system where part of the Reflex (plus Treflan or Prowl) is preplant incorporated into moist soil prior to planting (Table 6) with the rest of the Reflex plus another residual herbicide applied preemergence right after planting.

Table 6. The most effective options to eliminate emerged Palmer before planting in conventional systems.

CONVENTIONAL TILLAGE		
-----------------------------	--	--

Option 1	Option 2
Reflex 8-12 oz/A + Prowl/Treflan preplant incorporated 1 to 2 inches deep (preferably within 7 days of planting). <u>Make sure to follow with a PRE herbicide mix.</u>	Keep clean with tillage or herbicides

SELECTING A PREEMERGENCE (PRE) HERBICIDE – ALL COTTON CULTIVARS

Residual at-plant herbicides are needed in all Georgia fields. Unlike never before, herbicide resistance threatens the sustainability of our farms. The lack of new herbicide chemistry along with the overuse of some herbicides has led to serious issues in the development of herbicide resistance. The use of effective residual herbicides behind the planter is among the most important management approaches to mitigate resistance development and to maximize yield potential.

Research consistently shows maximum control is achieved with two effective residual herbicides applied in mixture within 24 hours of planting; include paraquat if Palmer is up. Georgia research has shown Warrant + Reflex, Direx + Reflex, Warrant + Direx, and Brake + Reflex or Warrant to be consistently effective (Table 7, below).

Table 7. Most effective herbicide options to apply preemergence (PRE) in cotton.

Preemergence Option	Comments
1. Warrant + Reflex	1. Cotoran can be used to effectively replace Direx in fields with minimal Palmer infestations or for improved control of other broadleaf weeds. 2. Use 10-12 oz/A PRE of Reflex for <u>most soil</u> types. 3. Warrant rate suggested by the manufacture is 48 oz/A; UGA research suggest in a Liberty or auxin-based systems that 32 oz/A is often more appropriate. 4. Direx use rate is typically between 10 and 20 oz/A with lower rates on lighter soils and in conditions where heavy rainfall/irrigation is expected. 5. Brake requires significant rain/irrigation to become active.
2. Direx + Reflex	
3. Warrant + Direx	
4. Brake + Reflex	
5. Brake + Warrant	

Reflex (fomesafen) tank mixtures are the most effective options for residual Palmer amaranth control. It requires very little rainfall/irrigation to activate, often activated with 0.3”, and it will lay on the soil for several weeks with minimal degradation. When comparing Warrant vs Direx as a Reflex tank mix partner one should consider the following: 1) Warrant offers more residual Palmer and spiderwort control and will sit on the soil longer waiting on an activating rainfall but 2) Direx offers the greatest ability to control emerged weeds, especially Palmer. A three-way combination of Reflex plus Warrant plus Direx usually only provides better control than the two-way combinations if very low rates are used or emerged weeds are present. Brake + Reflex is also extremely effective once activated; Brake needs at least 0.5 inch rainfall/irrigation for activation. Additionally for the grower frustrated with Reflex injury, a mixture of Warrant + Direx has proven effective in a “good” weed management system. Always, include paraquat + adjuvant with the PRE if weeds are emerged.

Replanting after the PRE

If previously used herbicides do not pose an injury risk, it is best to run the planter back in the original drill without any soil preparation if conditions permit. If reworking the seedbed is necessary then the following procedures are suggested:

Strip tillage: Rerun the strip-till rig which should include ripper shanks followed by planting; make certain the operation does not concentrate the previously applied herbicide in the planting zone. After

replanting, apply a PRE herbicide mixture that includes both a non-selective herbicide to control emerged weeds/cotton and a residual herbicide. The residual herbicide should be different chemistry than that used with the original planting. It is likely the residual herbicide used with replanting may offer limited residual Palmer control; thus, the first POST application may need to be made quickly.

Conventional Tillage: For those who do not have strip-tillage implements, using shallow tillage such as light disking can be helpful. Do not re-bed without first disking. Re-bedding without disking can lead to severe injury. The amount of time that has passed and the amount of rainfall that has occurred between herbicide applications and replanting will determine the need for additional herbicides. In general, additional herbicides will be needed when replanting but one should switch residual herbicide chemistry from that used during the first planting.

Killing emerged cotton: Roundup, paraquat, and/or Liberty are encouraged to control emerged weeds and cotton when replanting. Paraquat or Aim will control small emerged cotton. Liberty is also effective controlling cotton as long as it is not a cultivar tolerant to Liberty.

GLYPHOSATE (ROUNDUP) ALONE OR IN MIXTURES FOR TOLERANT COTTON

Most cotton cultivars now have tolerance to glyphosate; be certain the cultivars treated with glyphosate are tolerant or extreme damage will occur. Many brand names and formulations of glyphosate are available. Products vary in their concentration of active ingredient and their need for an adjuvant. Follow label recommendations.

Timing of Application

Brands of glyphosate with specific labeling for RR Flex cotton may be applied overtop or directed any time from cotton emergence until seven days prior to harvest. The maximum rate for any single application between crop emergence and the 60 percent open boll stage is 1.13 lb a.e./A. A total of 4.5 lb a.e. can be applied during this time frame. Hence, depending upon application rate, four to six applications can be made overtop or directed. An additional 1.55 lb a.e. can be applied from the 60-percent-open-boll stage until seven days prior to harvest. Regardless of label flexibility, growers should not overly rely on glyphosate; see the *Herbicide Resistance Management* section.

Tank Mixes with Glyphosate Applied Overtop

Acetochlor (Warrant) plus glyphosate can be applied after cotton is completely emerged but before first bloom. Warrant does not control emerged weeds but provides residual control of many grasses and small-seeded broadleaf weeds including tropical spiderwort. A second POST application of Warrant can be made if it was not applied PRE. Injury from POST applications is temporary when applications are made prior to the 9-leaf cotton stage; this application can cause minor stunting at times but no speckling on later-emerging leaves or adverse effect on yield or maturity is expected. The exception has been when additional adjuvants or insecticides are included in the mixture where severe injury is possible. Injury will also be greater if Warrant is applied when dew is on the cotton, when the weather is extremely hot and humid, and especially when soils are saturated.

Acetochlor (Warrant) vs. **S-metolachlor** (Dual Magnum). Although these herbicides are similar in many ways there are some distinct differences. Georgia research suggests Dual Magnum is much easier to activate and provides immediate Palmer amaranth control once activated while Warrant requires a few days after activation to become fully active. However, Warrant is far more effective when herbicides lay on the soil for 7 to 12 days waiting to be activated. Also, Warrant can be applied PRE to cotton while Dual Magnum should not. Neither product should be applied preplant.

Dimethenamid (Outlook) can be applied overtop of cotton in a mixture with glyphosate from the first true leaf stage until mid-bloom. Make only one application per year. Similar to S-metolachlor and acetochlor, dimethenamid has no activity on emerged weeds but it will provide residual control of pigweed species, including Palmer amaranth, and annual grasses. Research to date has shown that crop tolerance is similar to that with S-metolachlor or acetochlor.

Labeled grass herbicides (clethodim, fluazifop, quizaqlofop, and sethoxydim) can be mixed with glyphosate to control volunteer Roundup Ready corn.

Pyriithiobac (Staple LX) can be mixed with Roundup and applied overtop of RR Flex cotton from the cotyledonary stage until 60 days prior to harvest. Staple rates in this mixture range from 1.3 to 3.8 oz/A (prefer 2.7 oz/A or less) and will improve control of hemp sesbania, morningglory (except tall morningglory), spreading dayflower, glyphosate-resistant Palmer amaranth (assuming it is not also ALS-resistant) and tropical spiderwort. Staple also will give residual control of susceptible weeds, such as pigweed species, spurred anoda, and velvetleaf. Palmer amaranth resistant to Staple and other ALS inhibitors is somewhat common in Georgia.

Roundup plus Staple may cause temporary yellowing of the cotton bud. Research has demonstrated that cotton recovers quickly, and there is seldom an adverse effect on yield or maturity. On occasion, however, Staple applied overtop can cause moderate to severe injury. The potential for significant injury appears to be greater when the herbicide is applied during or shortly before a period of cool temperatures. In addition to cool temperatures, other stresses such as wet weather, seedling disease, or thrips damage may worsen injury. Slower recovery from Staple injury has particularly been noted on cotton infested with Thrips.

S-metolachlor (Dual Magnum, many generics) can be applied overtop of cotton that is at least 3 inches tall until 100 days prior to harvest. Crop injury from a mixture of Roundup plus Dual Magnum overtop is typically minor, with only necrotic speckling noted on leaves exposed to the spray. Injury from POST applications is temporary when applications are made prior to the 9-leaf cotton stage; this application can cause minor stunting at times but no speckling on later-emerging leaves or adverse effect on yield or maturity is expected. The exception has been when additional adjuvants or insecticides are included in the mixture where severe injury is possible. Injury will also be greater if Dual Magnum is applied when dew is on the cotton, when the weather is extremely hot and humid, and when soils are saturated.

Mixing Dual Magnum with Roundup will not improve control of emerged weeds. However, if timely rainfall for activation is received, Dual Magnum can provide residual control of most annual grasses (only suppression of Texas panicum), pigweed species (including Palmer amaranth), tropical spiderwort, and doveweed with suppression of yellow nutsedge and spreading dayflower.

Both metolachlor and S-metolachlor are available. Growers should be aware that metolachlor is less effective than S-metolachlor. Metolachlor is a mixture of four stereoisomers. Two of the isomers (referred to as S-metolachlor) are herbicidally active, whereas the other two isomers (referred to as R-metolachlor) have little herbicidal activity. Products whose labels designate S-metolachlor contain primarily the active isomers. Labels for products containing metolachlor specify the same rate of formulated product per acre as those containing S-metolachlor, hence growers are getting less of the active form of the herbicide when using metolachlor products. One would have to

increase the rate of a metolachlor product by 50 percent to get the same activity as a product containing S-metolachlor.

A prepackaged mixture of the potassium salt of Roundup plus Dual Magnum (Sequence) is available. At 2.5 pt/A, this premix provides 0.7 lb a.e. of Roundup + 1 pt of Dual Magnum.

Trifloxysulfuron (Envoke) can be mixed with certain brands of Roundup and applied overtop of cotton from the five (prefer 7)-to-12-leaf stage for improved nutsedge, morningglory, and smartweed control. Injury is of significant concern; thus, directed applications are strongly encouraged. The mixture is expected to cause some yellowing in the cotton terminal and shortening of internodes. Less response is typically observed on larger cotton.

Tank Mixes with Glyphosate Directed

In almost every case where Roundup is being directed, it is advisable to add a tank-mix partner to improve control of certain emerged weeds and/or to provide some residual control. *Tank mixes are also recommended as part of a resistance management program.* Potential tank-mix partners with Roundup postemergence-directed include Aim, Caparol, diuron, Dual Magnum, Envoke, ET, Fierce, Outlook, Staple, Valor, Warrant, and Zidua.

Acetochlor (Warrant), **dimethenamid** (Outlook), **pyroxasulfone** (Zidua), or **S-metolachlor** (Dual Magnum, many others) mixed with Roundup will not improve control of emerged weeds. However, if reaching the soil and activated by rainfall, they will provide residual control of annual grasses and small-seeded broadleaf species, including Palmer amaranth. Warrant can be directed anytime up to first bloom of cotton. Zidua can be directed from the five-leaf stage to first bloom; make sure not to apply Zidua topically. Dual Magnum can be directed to cotton that is at least 3” tall through 80 days before harvest and Outlook can be directed from first true leaf stage through mid-bloom.

Carfentrazone (Aim) and **pyraflufen ethyl** (ET) will improve morningglory control when mixed with Roundup. Additionally, Aim will provide excellent control of tropical spiderwort less than 4 inches. Cotton should be at least 20 inches tall, and the spray must be directed precisely to the woody portion of the stem. Spray contact with green stem tissue will cause injury. This combination does not provide residual control.

Diuron (Direx, others) or prometryn (Caparol, others) mixed with Roundup will improve control of Palmer amaranth and many other broadleaf weeds; for larger morningglory one likely needs to include Envoke in the mixture as well. Products containing Direx applied at 1.5 pt/A or products containing prometryn applied at 2 pt/A will provide some residual control of small-seeded broadleaf weeds, including pigweed, if an activating rainfall is received. Direx is generally more effective on pigweed than Caparol. Cotton should be at least 12” tall before directing these products at these rates. Occasionally, mixing these herbicides with Roundup will reduce grass control compared to Roundup alone or at least delay death of the grasses. This is most likely to occur when grasses are large and/or under dry growing conditions. Use the maximum glyphosate rate labeled when applying these mixtures.

Flumioxazin (Valor SX, Valor EZ, others) mixed with Roundup will improve control of doveweed, Florida pusley, tropical spiderwort, and morningglory while also providing good residual control of many weeds including Palmer amaranth, pusley, and purslane. Cotton should be at least 18” tall with a completely “woody” stem before this combination is precisely directed to the bottom 1- to 2-

inches of the cotton stem. Add nonionic surfactant at 1 qt per 100 gal spray solution if Roundup brand requires adjuvant. DO NOT use crop oil concentrate, methylated seed oil, organo-silicone adjuvants, or any adjuvant product containing these. Valor has a very favorable rotational package.

Flumioxazin plus pyroxasulfone (Fierce) can be used in the same manner as Valor, discussed above. It will improve control of many emerged weeds while providing excellent residual control of grasses and many broadleaf weeds, including Palmer amaranth. Fierce will provide better residual control of grasses and some small-seeded broadleaf weeds when compared to Valor.

Pyrithiobac (Staple LX) mixed with Roundup will improve control of hemp sesbania, morningglory (except tall morningglory), spreading dayflower, tropical spiderwort and glyphosate-resistant Palmer amaranth. Staple can also provide residual control of susceptible species such as prickly sida, non-resistant pigweed species, spurge, velvetleaf, and spurred anoda.

Trifloxysulfuron (Envoke) mixed with Roundup will improve control of nutsedge and larger morningglory. Cotton should be at least 6 inches tall. Envoke has some residual activity on susceptible broadleaf weeds if activated.

Glyphosate Mixtures versus Other Directed Herbicides

On glyphosate-tolerant cotton, one has the option of directing either Roundup or a traditional herbicide combination such as Direx + MSMA. Better broadleaf weed control, especially Palmer amaranth, is sometimes obtained when traditional directed herbicides are used. If, however, grasses are a predominant problem, and they are larger than 1 inch, Roundup mixtures are better options.

GLUFOSINATE (LIBERTY) ALONE OR IN MIXTURES FOR TOLERANT COTTON

Most cotton cultivars now have tolerance to both glyphosate and glufosinate; be certain the cultivars treated with glufosinate are tolerant or extreme damage will occur.

Timing of Liberty (glufosinate) Application

The Liberty label currently allows three applications of 29 oz/A, for a seasonal total of 87 oz/A. Alternatively, one can apply 30 to 43 oz/A once, followed by one more application of 29 oz/A, for a seasonal total of 72 oz/A. Liberty can be applied from cotton emergence until the early bloom stage.

Application of Liberty should be based on weed size rather than crop size. The optimum weed size for treatment varies by weed species and growing conditions. In general, broadleaf weeds should be no more than 4 inches tall. Pigweed species, including Palmer amaranth, and annual grasses should be no more than 3 inches tall. Under dry conditions, weed size should be less than 2 inches. Goosegrass and tropical spiderwort likely will not be adequately controlled. Optimum timing for the first application generally occurs 14 to 18 days after cotton emergence, with optimum timing of the second application 14 to 18 days after the first application assuming the first application is timely. For situations where the pigweed is too large to control with the first application, a second application should be made 5 to 7 days later.

Protecting Liberty

Because of weed resistance to Roundup and because the development of new new herbicide modes of action are extremely rare, Liberty (generics) will continue to play a significant role in cotton weed management. It is imperative that growers follow sound resistant management strategies to avoid or delay selection for resistance to Liberty. In addition to diversifying and integrating other herbicides

and cultural practices into a management program, growers are strongly encouraged to maximize Liberty application procedures while making no more than two applications per year.

PROTECTING LIBERTY FOR FUTURE SUSTAINABILITY: THE DECISION IS YOURS!
<ol style="list-style-type: none"> 1. Do not make more than 2 applications of Liberty (generics) per year. 2. Spray Liberty when the biggest pigweed in the field is 3 inches or smaller. 3. Never ever use a reduced rate! 4. Avoid applications within 1.5 hr of sunrise and 1 hr of sunset. 5. Apply at 15+ GPA using a speed, spray tip, and pressure that delivers a medium/course spray droplet. 6. Integrate herbicide programs with 1) cover crops, 2) tillage, and/or 3) hand weeding.

Application Time of Day for Herbicides Impacts Weed Control

Activity of Liberty, Roundup, dicamba, 2,4-D, Reflex, and Diuron is influenced by the time of day in which they are applied. For Roundup, dicamba, and 2,4-D, applications near sunrise or sunset cause below average performance on Palmer amaranth. *Liberty is the most vulnerable and should not be applied within 1.5 hours of sunrise and 1 hour of sunset (Fig 10).*

Figure 10. Palmer amaranth control by Liberty system as influence by time of day. Evaluation at harvest.

Application Equipment

Liberty behaves much like a contact herbicide, so good spray coverage is necessary. Ideally, the spray volume is at least 15 gal/A. Ultimately the goal with Liberty is to achieve thorough spray coverage thus growers must understand the relationship of speed, pressure, and nozzle type to achieve this goal. *“Dicamba” nozzles may not be satisfactory for Liberty applied alone.*

Tank Mixes with Liberty Applied Overtop

Acetochlor (Warrant), **dimethenamid** (Outlook), **pyrithiobac** (Staple LX), and **S-metolachlor** (Dual Magnum, others) can be mixed with Liberty. Warrant can be applied after cotton is completely emerged but before first bloom and a second POST application can be made if Warrant was not applied PRE; Outlook can be applied from 1-leaf cotton through the second week of bloom; Dual Magnum can be applied overtop to cotton at least 3 inches until early bloom or 100 days before harvest (whichever is more restrictive). Staple can be applied overtop of cotton from full cotyledonary cotton through early bloom or 60 d before harvest (whichever is more restrictive).

Warrant, Outlook, and Dual Magnum do not improve control of emerged weeds but will provide residual control of many grass, small seeded broadleaf weeds, and tropical spiderwort if activated. Staple mixed with Liberty may improve control of emerged pigweed and spiderwort while providing residual control of numerous broadleaf weeds including non-resistant pigweed (see weed response to herbicides in appendix).

In Liberty Link cotton, mixtures of Liberty plus Dual Magnum, Warrant or Staple will be similar to that noted with respective comparable Roundup mixtures. Injury is expected to be slightly higher in XtendFlex cotton.

Glyphosate. In cotton tolerant to glyphosate and glufosinate, growers have the option of using both Roundup and Liberty, either sequentially or in a tank mix. This mixture has become common for the control of broadleaf and grass weeds infesting cotton. In general, the tank-mix will provide excellent control of broadleaf weeds that are sensitive to the herbicides. For grasses, the tank mixture is often less effective than glyphosate alone but more effective than glufosinate alone. A tank-mix is not suggested for goosegrass or perennial grasses (e.g., bermudagrass or johnsongrass); instead, use sequential applications with Roundup applied 3 to 5 days prior to Liberty.

Glufosinate in a Directed Application

Liberty can be directed in cotton tolerant to glufosinate up to the early bloom stage and can be directed alone or mixed with herbicides such as Aim, Direx (others), Caparol (others), or Staple LX. Most Liberty-based systems will include two overtop applications of Liberty; thus, growers are encouraged to utilize conventional chemistry at layby for resistance management.

WEED MANAGEMENT IN XTENDFLEX COTTON

XtendFlex cotton has tolerance to glyphosate (Roundup, etc), glufosinate (Liberty, etc), and dicamba (Engenia, XtendiMax). Herbicides discussed under *Glyphosate Alone and in Mixes for Tolerant Cotton* and *Glufosinate Alone and in Mixes for Tolerant Cotton* can be used in XtendFlex cotton.

Applicators must have a certified pesticide license and also have attended the Using Pesticides Wisely training before applying Engenia, XtendiMax, or Tavium in Georgia; no other dicamba formulation is labeled for applications in-crop. Use of labeled dicamba formulations will reduce, but not eliminate, the potential for volatility. Additionally, postemergence applications of these herbicides must be supported by sound at-plant herbicide mixtures, a directed layby, cover crops or tillage, and hand removal of all Palmer amaranth escapes.

Only certain herbicides are allowed to be tank-mixed with *Engenia, XtendiMax or Tavium*. Permissible tank mixtures with Engenia or XtendiMax can be found online at www.engeniatankmix.com or www.xtendimaxapplicationrequirements.com and those for Tavium can be found at www.TaviumTankMix.com

Application Timing

Currently, the U.S. EPA and manufactures of Engenia, Tavium, and XtendiMax are in discussions regarding 2022 label requirements and restrictions. One must review 2022 labels prior to use. A general discussion regarding application timings/requirements based on labels at the time of publication follow.

Engenia and XtendiMax can be used for *burndown/early preplant, preplant, at-planting, or preemergence*; a maximum of two applications with each application applying no more than 0.5 lb ai/A (XtendiMax 22 oz/A; Engenia 12.8 oz/A). *Two additional postemergence applications can be made in-crop*, again each with a maximum rate of 0.5 lb ai/A. Current labels require applications to be completed by July 30. Dicamba should almost always be mixed with a labeled glyphosate formulation. Sequential applications must be separated by at least 7 days. Applications should be timely; broadleaf weeds should be less than 4 inches tall with Palmer amaranth needing to be less than 3 inches. To avoid the potential for significant visual damage, applications after cotton reaches the 8-leaf stage of growth should be directed.

Applied as part of the *preplant burndown program*, dicamba can help control weeds such as glyphosate-resistant horseweed and cutleaf eveningprimrose (see *Burndown* discussion). Engenia or XtendiMax can be mixed with selected brands of glyphosate, Valor and diuron when applied preplant. Although the plant back interval is removed for dicamba in dicamba-tolerant cotton, the standard plant back interval for Valor and diuron still apply.

Preemergence application of dicamba is generally discouraged. Although dicamba can give good residual control of some broadleaf weeds if the weather cooperates, the control is short-lived (10 days or less), and it is quite inconsistent. Preemergence application of dicamba should be considered only in situations where crop injury is a serious concern with all other residual herbicides and where paraquat is not a good burndown option. An example might be large horseweed not adequately controlled by an earlier burndown.

Postemergence tank mixtures for Engenia or XtendiMax include selected brands of glyphosate, selected brands of clethodim, Dual Magnum, Staple, or Warrant. Engenia can also be mixed with Outlook. Tavium is a premix of XtendiMax and Dual Magnum and may be applied over tolerant cotton through the 6-leaf stage or July 30, whichever comes first. Again, contact your local extension agent to determine if these application restrictions have changed for Georgia applicators.

Drift reduction adjuvants (DRA'S)

DRA's are required for many in-crop dicamba applications as influenced by tank-mix partner, websites provide requirements and approved DRA products.

Volatility Reduction Agents (VRA's), pH Buffering Adjuvant

These products are required when applying labeled herbicides in dicamba-tolerant cotton to reduce volatility; use only products approved on the manufactures web site at recommended rates. These products potentially buffer against significant changes in solution pH and prevent the formation of dicamba acid by scavenging extraneous protons. The photograph on the right shows the potentially enormous benefit that these products can have in some environments.

Soybean damage from dicamba volatility as influenced by volatility reduction adjuvant (VRA).

WEED MANAGEMENT IN ENLIST COTTON

Certain Phytogen varieties, designated as W3FE, carry the Enlist trait and are tolerant of 2,4-D (Enlist One, Enlist Duo), glyphosate (Roundup, etc), and glufosinate (Liberty, etc). In contrast to WRF varieties, varieties designated as W3FE have essentially complete tolerance of glufosinate. Any of the programs discussed above under *Glyphosate Alone and in Mixes for Tolerant Cotton* and *Glufosinate Alone and in Mixes for Tolerant Cotton* can be used in Enlist cotton. Additionally, Enlist One (contains choline salt of 2,4-D) and Enlist Duo (contains glyphosate plus the choline salt of 2,4-D) can be applied. These are the only brands containing 2,4-D that can be applied to Enlist cotton. Use of these brands will reduce, but not eliminate, the potential for volatility. *Additionally, postemergence applications of these Enlist One or Enlist Duo must be supported by sound at-plant*

herbicide mixtures, a directed layby, cover crops or tillage, and hand removal of all Palmer amaranth escapes.

Permissible tank mixtures with Enlist One or Enlist Duo can be found online at www.enlisttankmix.com. Drift reduction agents are not required with Enlist One tank mixes, although certain ones are approved for application.

Application Timing

During January of 2022, Enlist One and Enlist Duo registrations expire. The manufacture and the US EPA are currently developing a revised label. It is unknown what changes in requirements or restrictions may be in place for the 2022 crop; thus, one must study the new label before use. A general discussion regarding application timings/requirements based on labels at the time of publication follow.

Enlist One and Enlist Duo can be applied *any time prior to planting, preemergence after planting, and postemergence*. An advantage of Enlist cotton is that there is no waiting period between *preplant application* and planting. However, a timely burndown application at least 14 days ahead of planting is still encouraged for fields infested with weeds or broadleaf cover crops. Valor and/or diuron are critical components to a burndown program and each can be used with Enlist herbicides, see website for specially approved brands.

A good *preemergence* herbicide program is absolutely essential in Enlist cotton regardless of the postemergence program; however, 2,4-D choline should be considered as a preemergence application only in situations where burndown herbicides did not effectively control weeds prior to planting. Far better residual herbicides are available for use at-plant.

Enlist One or Enlist Duo can be applied *postemergence* any time from cotton emergence until the mid-bloom stage. Apply postemergence no more than twice per season. Separate applications by at least 12 days. Applications should be timely; broadleaf weeds should be less than 4 inches tall with Palmer amaranth needing to be less than 3 inches. To avoid the potential for significant visual damage, applications after cotton reaches the 8-leaf stage of growth should be directed. Enlist One can be applied postemergence in mixture with specific brands of glyphosate, specific brands of glufosinate including Liberty, Dual Magnum, and Warrant.

POSTEMERGENCE HERBICIDES APPLIED OVERTOP FOR ANY COTTON VARIETY

Pyrithiobac (Staple LX) can be applied overtop of cotton from the cotyledonary stage until 60 days before harvest. Two applications per year are allowed as long as the total applied per season does not exceed 5.1 fl oz. If applied in a timely manner, Staple controls many broadleaf weeds (see weed response charts in appendix) but does not adequately control lambsquarters, ragweed, sicklepod, spurge, tall morningglory, or tropic croton. Most susceptible broadleaf weeds should not be taller than 3 inches; prickly sida and Palmer amaranth must be 1 inch or less. Palmer amaranth resistant to Staple and other ALS-herbicides is present in Georgia.

Tank mixes of Staple with grass herbicides such as Select, Fusilade, Assure II, and Poast are not recommended because antagonism (reduced grass control) is often observed. When making sequential applications of Staple and a postemergence grass-control herbicide, apply the Staple at least three days before or one day after application of the grass-control herbicide. Longer intervals between applications of the two herbicides are preferred.

Trifloxysulfuron (Envoke) can be applied overtop of cotton with a minimum of five (prefer 7) leaves up to 60 days prior to harvest. Injury from topical applications is a concern; thus, directed applications are strongly encouraged. In cotton larger than about 10 inches, directed or semi-directed application may improve spray coverage on weeds below the crop canopy as well. For best control, weeds should be less than 3 inches tall. Envoke controls or suppresses nutsedge plus a number of broadleaf weeds (see weed response charts in appendix) but does not control jimsonweed, prickly sida, spreading dayflower, or spurred anoda, and it is not adequately effective on tropic croton. Control of Palmer amaranth is usually inadequate.

Staple and Envoke have the same mechanism of action; thus, ALS-resistant Palmer amaranth will not be controlled by either product.

Cotton is often injured by Envoke applied overtop. Injury is expressed as yellowing in the growing point and shortened internodes. Some degree of crop response can almost always be expected. In most cases, the injury is relatively minor and the crop recovers. On occasion, however, moderate to severe injury has been observed. Smaller cotton appears to be injured more than larger cotton. Growers are encouraged to not apply the herbicide to cotton under stress from wet or dry weather or thrips. Also, carefully follow label directions for adjuvant usage and tank mixtures. Tank mixes of Envoke with grass control herbicides (such as Select, Poast, etc) should be avoided. Separate applications of Envoke and the grass-control herbicides by at least three days if the grass-control herbicide is applied first or five days if Envoke is applied first.

Grass-control herbicides. Clethodim (Select, others), fluazifop (Fusilade, others), quizalofop (Assure II, others), and sethoxydim (Poast, others) can be applied overtop of cotton from emergence through midseason. These products control annual and perennial grasses but are ineffective on nutsedge and broadleaf weeds. All of these products are safe on cotton and are effective when applied to small grasses under good growing conditions. However, Select and Poast tend to be more effective over a range of annual grass species and environmental conditions. Select, Fusilade and Assure II tend to be more effective on perennial grasses than Poast. When using any of these herbicides, follow label directions for application rates, application methods, use of adjuvants, and optimum grass size for treatment. Tank-mixing broadleaf herbicides such as Staple or Envoke with these postemergence grass-control herbicides is not recommended.

POSTEMERGENCE-DIRECTED HERBICIDES FOR ANY COTTON VARIETY

A number of herbicide combinations are available for directed application to any variety of cotton. More common options include Caparol + MSMA, Cobra + MSMA, Cotoran + MSMA, Direx + MSMA, and Valor + MSMA. Aim, Dual Magnum, Envoke, ET, Outlook, Staple, Warrant, and Zidua may be added to some (not all) of these combinations; follow the most restrictive requirements for products in tank mixtures for application timings, cotton stage of growth, etc.

The postemergence-directed herbicides listed above are primarily for annual broadleaf weeds and nutsedge. MSMA in these mixtures will control annual grasses less than 1". Except for Aim, ET, MSMA, and Cobra plus MSMA, the options listed above will also provide some residual control of sensitive weeds.

Diuron + MSMA has many strengths and is the most commonly used of these options. The mixture really only has two weed control weaknesses. *First*, it lacks control of larger (>4") morningglory.

When both Palmer amaranth and morningglory need to be controlled then one should consider including Envoke with the diuron + MSMA. *Second*, Diuron + MSMA lacks control of grasses larger than 1 inch. If Palmer amaranth is not problematic but grasses larger than 0.5” are an issue, Roundup mixtures in tolerant cotton will be more effective.

PREHARVEST HERBICIDE APPLICATION

Preharvest herbicide applications are of questionable value in most cases. Desiccating mature weeds likely will not increase harvesting efficiency nor reduce harvesting losses. The major exception would be fields heavily infested with viney weeds such as morningglory and cowpea. Lint staining from weeds has not been voiced as a significant problem in spindle-picked cotton. Desiccating weeds will more likely increase rather than decrease trash in cotton because gins can remove green plant parts more easily than finely ground, desiccated plant parts. However, if present in large quantities, extraneous green matter can increase the potential for overheating, rot, and stain if the cotton is packed into a module and the module is not properly monitored.

Annual Weeds

Aim or ET are also registered for use as defoliant. Good desiccation of morningglory and cocklebur has been observed with excellent spray coverage. Results on pigweed are usually not acceptable. These products will not desiccate grasses or sicklepod. See labels and the defoliation section regarding adjuvants and the potential for causing issues sticking cotton leaves.

Roundup can be applied after 60% of the bolls are open in non-tolerant cotton and can be applied to tolerant cotton until 7 days before harvest.

Paraquat. Either add 2 to 6 fl oz of product with standard defoliant or apply after cotton defoliation; confirm this use is on the label of the paraquat brand used. When applying after cotton defoliation and at least 80 percent of the bolls are open, the remaining bolls expected to be harvested are mature, and most of the cotton leaves have dropped, apply 11 to 21 oz/A of Gramoxone 3 SL; see label for rates of other brands. Broadcast in a minimum of 20 gallons of water per acre and add 1 pint of nonionic surfactant per 100 gallons of water. Initiate harvest as soon as leaves are toughened (the “green” is removed) but before foliage becomes brittle; usually one should wait 5 days and then pick as soon as possible. Paraquat will desiccate most annual weeds with Florida pusley being an exception; desiccation of wild radish is often not ideal as well. Cotton must be harvested in a timely manner, bark and cotton plant death can occur rapidly. Although rare, cotton lint may turn a light purple color soon after application.

Perennial Weeds

Glyphosate (Roundup) can be applied in the fall to control or suppress perennial weeds for the following year. For weeds that will receive adequate coverage with the defoliation application, glyphosate at a rate of 0.75 to 1.5 lb a.e./A may be tank-mixed with the defoliant. Apply when at least 60 percent of the bolls are open. Alternatively, glyphosate may be applied after defoliation which may be preferred in rank cotton to improve spray coverage. Additionally, a separate application of glyphosate allows treatment of only the infested areas.

For perennial weeds, such as bermudagrass, nutsedge, trumpetcreeper, horsenettle, common milkweed, and hemp dogbane, glyphosate-defoliant tank mixes may not provide adequate coverage and a follow-up spot application may be needed. Suggested application rates are 1.5 lb ae/A for johnsongrass, 2.25 lb ae/A for nutsedge, trumpetcreeper, common milkweed, and bermudagrass, and 3 lb ae/A for horsenettle and hemp dogbane. To reduce costs, spot-spray only infested areas.

Glyphosate should be applied at least 7 days before the first killing frost for all weeds.

MANAGING THE MOST TROUBLESOME WEEDS IN THE COTTON CROP

Bermudagrass: For success, fall applications are needed. At least 7 days before frost, apply Roundup at 2.25 lb a.e./A in single application or two applications 7 days apart at 1.13 lb ae/A. During the following season implement both Roundup and postemergent graminicides when feasible. Postemergence graminicides (Select, Select Max, Fusilade DX, Assure II) are effective options when bermudagrass has runners less than 6"; however, a tank mix of Roundup plus a graminicide would likely be the most effective option when labeled.

Doveweed: Roundup will only provide suppression while Liberty has even less activity. Dual Magnum and Warrant will control doveweed if activated before germination. Paraquat preplant or through hooded sprayers will control emerged doveweed. And, directed applications of Valor plus MSMA, Valor plus Roundup, and diuron plus Roundup are fairly effective on emerged plants.

Florida pusley: The key for control begins with applying residuals prior to emergence. Treflan, Prowl, Cotoran, diuron, Valor, and Warrant control this weed if applied properly and activated. Additionally, one should include residual herbicides in with POST and layby applications to prevent the weed from continually emerging. Florida pusley can be controlled by Roundup but ONLY if applied at the full rate when the weed is very small (1" or less) and under ideal conditions; multiple applications are often necessary. Roundup is more effective than Liberty. Dicamba or 2,4-D in mixture with Roundup will improve control.

Glyphosate-resistant common ragweed: Common ragweed resistant to Roundup is present in North Carolina. Common ragweed emerges earlier than many other summer annual broadleaf weeds. Valor applied early burndown in combination with Roundup plus 2,4-D or dicamba will provide residual control of early emerging common ragweed. Brake plus Reflex, Cotoran, or Reflex plus diuron applied preemergence are effective. Common ragweed can be controlled postemergence with Liberty while Envoke also provides activity. Most of the conventional directed herbicide combinations as well as dicamba and 2,4-D are also effective.

Glyphosate-resistant Palmer Amaranth: Palmer amaranth is Georgia's most problematic pest. It is imperative that growers continue to use sound herbicide programs but also integrate these programs with other control measures, such as 1) hand-weeding, to remove escapes before seed are produced, 2) deep turning to reduce the number of plants emerging (ideally wait 3.5 to 4 years or more before repeating), and/or 3) using a cover crop mulch to suppress Palmer emergence in conservation tillage. Also, it is imperative that Palmer amaranth is controlled in crops rotated with cotton, and this should be done with minimal reliance on PPO (Reflex, Valor) inhibitors, Liberty and dicamba. Because these herbicides are critical to control glyphosate-resistant Palmer amaranth in cotton, it is a grower's best interest to prevent or at least slow further selection for resistance to these herbicides.

Suggested herbicide programs are available on circulars at www.gaweed.com or at the local Extension office. For conventional tillage systems, Treflan or Prowl are effective on Palmer amaranth if shallowly and uniformly incorporated. Additionally, Georgia has a label allowing Reflex to be split-applied with 8-12 oz/A of Reflex mixed with Treflan or Prowl and shallowly incorporated in the soil followed with a preemergence application of Reflex at 8-10 oz/A plus an additional residual herbicide.

In strip-till systems, an early preplant burndown application of Roundup plus either 2,4-D or dicamba is suggested for good burndown of a wide range of species, including glyphosate-resistant horseweed, wild radish, and cutleaf eveningprimrose. Valor should be included in this burndown application providing excellent residual Palmer amaranth control. This can be very important if timely rainfall is not received following planting to activate the preemergence herbicides. If Palmer amaranth is already emerged and greater than 1 inch in height at time of burndown, the addition of diuron will be beneficial in controlling emerged plants. If Palmer amaranth is present just prior to planting then the most effective option is paraquat + Direx plus Crop Oil. Make sure to control the weed prior to planting. *Follow appropriate herbicide plantback intervals.*

Regardless of the tillage system, a strong preemergence program is needed. Apply one of the preemergence options noted in Table 4 (*selecting PRE herbicide section*) within 24 hours of planting, and include paraquat plus adjuvant with the at-plant herbicide if weeds are emerged.

For most fields, two timely postemergence applications will be needed regardless of cotton technology planted. Many growers are trying to avoid layby applications, but research has clearly shown these applications are critical to achieve the goal of mitigating additional Palmer amaranth seed being added to the soil-seed bank, which is critical for overall farm sustainability.

Goosegrass: All fields must begin free of this pest at planting and should include a residual at-plant herbicide such as Warrant or Prowl. Roundup is an effective option but only if the weed is small, the full glyphosate rate is applied, and conditions are favorable. The addition of residual herbicides such as Dual Mangu, Outlook, or Warrant should be included with Roundup. Liberty is marginally effective on goosegrass at best. Mixing Roundup and Liberty will reduce the activity of Roundup on goosegrass; thus, for goosegrass apply Roundup without Liberty if possible. POST grass herbicides can also be effective but must be applied very timely; these products can be mixed with Roundup but mixtures with Liberty are quite antagonistic. Goosegrass resistant to Roundup and POST grass herbicides are present in nearby states.

Hemp sesbania: Currently no data exists for the weeds response to Liberty. For Roundup, hemp sesbania is very difficult to control after the first true leaf. Data from other states show Roundup + 2,4-D or dicamba mixtures should provide very good control. When auxins cannot be used and the weed is expected to be a problem, soil-applied herbicides such as Cotoran are in order. Follow with Roundup plus Staple postemergence and a postemergence-directed application of a conventional herbicide combination including Cobra or Envoke. Envoke overtop of cotton would also be an option but since cotton must be at least 5-leaf (prefer 7) before application, sesbania may be greater than 3” at time of treatment which would likely end up providing poor control.

Morningglory: Cotoran preemergence is useful in heavily infested fields. Liberty, 2,4-D or dicamba provide outstanding control of emerged plants as long as the appropriate rate, weed size, and weed coverage are achieved. For Roundup, a single application rarely provides control. Thus, for morningglory 3 inches or larger (except tall morningglory), the addition of Staple with Roundup is an effective option. Envoke is also a very effective option on *Ipomoea* morningglory but when mixed with Roundup it should be applied as a sloppy-directed application to avoid crop injury, if possible.

At time of layby, conventional chemistries such as MSMA plus Caparol, Cobra, diuron, or Valor would be more effective than Roundup. Diuron plus MSMA or Roundup has become standard layby mixtures; however, the addition of Envoke with these mixtures is encouraged. See labels for

application timings and cotton sizes. For fields where morningglory emerge late in the season, including Staple and Cotoran with the layby would offer the most effective residual activity.

Nutsedge: Although Liberty provides a visual perception of control, it really is not an effective option. Two applications of Roundup at the maximum use rate normally provide adequate control of nutsedges. Good results also have been obtained with the full rate of Roundup applied overtop followed by a directed application containing MSMA at 2.5 pt/A or Envoke at 0.15 oz/A. In severely infested fields, best results will be obtained with two overtop applications of Roundup 7 to 10 days apart at the full rate followed by a directed application including MSMA and/or Envoke.

Perennial broadleaf weeds, such as horsenettle, trumpet creeper, common milkweed, and hemp dogbane, are primarily a problem in conservation tillage. Soil-applied herbicides will not control perennial broadleaf weeds. New Enlist and XtendFlex technologies allowing sequential applications of dicamba or 2,4-D mixed with Roundup will prove beneficial in the control of these perennial broadleaf weeds.

For fields where auxin herbicides cannot be used, control will be difficult. Horsenettle can be controlled with postemergence-directed herbicide combinations containing MSMA. Perennial broadleaf weeds can be suppressed or controlled with multiple applications of Roundup applied to tolerant cotton. Later applications are generally more effective on perennials, and two applications are more effective than one. Directed sprays are likely far more effective with applications made during mid- or late-season because of improved coverage.

Curly dock is best controlled by a preplant application of Harmony Extra.

Roundup Ready corn (volunteer): Assure II, Fusilade DX, Select or Select Max may be applied alone or mixed with Roundup to control Roundup Ready corn in Roundup Ready cotton.

Roundup Ready soybean (volunteer): Liberty will be extremely effective in controlling RR soybean as long as it is not also Liberty tolerant and the soybean is small. Similarly, dicamba applied to non-tolerant volunteers will be extremely effective.

For a Roundup-based program, Cotoran preemergence will be beneficial. Envoke applied overtop of soybeans with less than six trifoliolate leaves is the most effective postemergence option; control may be inadequate once soybean reaches 12". Staple POST typically does not control soybean. However, Staple applied to three- to four-trifoliolate soybean followed by a directed application of Caparol or diuron plus MSMA as well as any Envoke mixture may provide adequate control.

Tropical spiderwort: Dual Magnum and Warrant offer the greatest level of residual control in cotton; *well-placed residual herbicides are the key to a successful spiderwort management program.* Paraquat, Roundup + Aim, Roundup + 2,4-D, Roundup + dicamba (two applications), Roundup + Staple, and Direx + MSMA offer the greatest opportunity to control emerged plants. The addition of residual herbicides in conjunction with these POST treatments will be needed. Liberty is not effective; Roundup actually provides better control.

COTTON WEED CONTROL

A. Stanley Culpepper, Extension Agronomist—Weed Science

WEED	HERBICIDE	MOA	BROADCAST RATE/ACRE		REI/PHI (Hours or Days)	REMARKS AND PRECAUTIONS
			AMOUNT OF FORMULATION	LBS ACTIVE (AI or AE)		
PRE-PLANT BURNDOWN—ANY VARIETY						
Emerged primrose, wild radish, spiderwort, small horseweed. Data suggests the <i>choline</i> formulation of 2,4-D has reduced volatility potential when compared to other 2,4-D formulations.	2,4-D amine 4S 4.7S 5S	4	12–32 fl oz 10–25 fl oz 9–22 fl oz	0.38–0.95	48 H/ N/A	The MOST CONSISTENT and effective burndown program for winter weeds in Georgia is a 2,4-D application in February when weeds are small and herbicide coverage is adequate followed by <i>glyphosate</i> or <i>paraquat</i> mixtures at or near planting. Most, but not all brands, may be applied 30 days prior to planting cotton. PRIMROSE: apply 0.38 lb ai/A RADISH: apply 0.5–0.75 lb ai/A HORSEWEED: apply 0.75+ lb ai/A <i>Glyphosate</i> -RESISTANT HORSEWEED: apply 0.95 lb ai/A
	2,4-D choline Enlist One 3.8S	4	24–32 fl oz	0.7–0.95	48 H/ N/A	Apply at least 30 days ahead of planting any variety not containing the Enlist trait. <i>See section below for cotton with the Enlist trait.</i> Current labeling allows mixtures with several products including numerous <i>glyphosate</i> formulations, Direx, Valor, and Liberty. Be certain to study the label regarding requirements for training, buffers, wind speeds, ground speeds, spray tip requirements, and boom heights. User also must review website www.enlisttankmix.com for approved adjuvants, drift reduction agents, and tank mixtures.
Burndown of mature primrose and morning glory. Inadequate control of immature radish, pigweeds over 3" or grain cover crops. Mixtures with <i>glyphosate</i> are quite effective except on large grasses (better than Liberty alone but less than Roundup alone).	<i>glufosinate</i> Liberty 2.34S	10	29–43 fl oz	0.53–0.79	12 H/ N/A	Application can be made prior to cotton emergence. To maximize control: >15 GPA water volume, thorough spray coverage, warm temperatures, high humidity, bright sunlight, good soil moisture, and do not spray within 1.5 hours of sunrise or 2 hours of sunset. For Palmer amaranth, apply 29 oz/A when less than 3"; 32 oz/A when 3"; 36 oz/A when 4"; and 43 oz/A when taller than 4". Cheetah and Interline have been tested and performed similarly to Liberty, see labels. Other brands are available.
Burndown of emerged annual weeds, but does not adequately control primrose, geranium, large radish, field pansy, resistant horseweed, or resistant Palmer amaranth. <i>For ryegrass, spray glyphosate and follow with paraquat 5 to 7 days later.</i>	<i>glyphosate</i> 4S (3 lb ae) 5.4 S (4 lb ae) 5S (4.17 lb ae) 5.5 S (4.5 lb ae) 5.88S (4.8 lb ae) 6S (5 lb ae)	9	32–96 fl oz 24–72 fl oz 23–68 fl oz 22–64 fl oz 21–60 fl oz 19–58 fl oz	0.75–2.25 (lb ae)	4H/ N/A	Apply any time prior to planting. Sequential applications can be made not to exceed 3.7 lb ae/A for burndown. Lower rates for annual weeds and higher rates for perennial weeds. <i>Control of cover crops:</i> Wheat < 12": 0.56 lb ae Wheat > 12": 0.75 lb ae Rye < 12": 0.56 lb ae Rye > 12" (no seed head): 1.13 lb ae Rye > 12" (seed head): 0.56 lb ae

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

WEED	HERBICIDE	MOA	BROADCAST RATE/ACRE		REI/PHI (Hours or Days)	REMARKS AND PRECAUTIONS
			AMOUNT OF FORMULATION	LBS ACTIVE (AI or AE)		
PRE-PLANT BURNDOWN—ANY VARIETY <i>(continued)</i>						
Improved control of henbit, chickweed, Carolinageranium, and wild radish compared to <i>glyphosate</i> alone. Use Harmony Extra or Nimble to improve control of curly dock.	<i>glyphosate</i> + <i>thifensulfuron</i> + <i>tribenuron</i> FirstShot SG 50 SG	9 + 2 + 2	see <i>glyphosate</i> + 0.5–0.8 oz	0.75–2.25(lbae) + 0.008–0.013 + 0.008–0.013	12 H/ N/A	Apply at least 14 days prior to planting. Include nonionic surfactant at 1 qt/100-gal spray or crop oil concentrate at 1 gal/100-gal spray.
	<i>glyphosate</i> + <i>thifensulfuron</i> + <i>tribenuron</i> Harmony Extra SG with TotalSol 50SG or Harmony Extra, Nimble 75WDG	9 + 2 + 2	see <i>glyphosate</i> + 0.75 oz 0.5 oz	0.75–2.25(lbae) + 0.0156 + 0.0078	12 H/ N/A	
Burndown of emerged annual weeds 3" or less. Does not control immature primrose, large horseweed, curly dock, swinecress, immature radish, or large grasses. For ryegrass, spray <i>glyphosate</i> first and <i>paraquat</i> 5–7 days later.	<i>paraquat</i> 2SL 3SL	22	2.5–4pt 1.7–2.7pt	0.63–1	24 H/ N/A	EPA has restricted the use of <i>paraquat</i> to certified applicators ONLY and applicators must take a specialized training before use. Apply any time prior to planting. Add nonionic surfactant at 2 pt/100 gal or crop oil concentrate at 1 gal/100 gal of spray mix. Apply 0.63 lb ai for wheat and 0.5 lb ai for rye cover crop; cover crops must be mature (seedheads present) for adequate control. Mixtures with <i>diuron</i> are usually far more effective.
Burndown of emerged annual weeds and provides residual control if <i>diuron</i> is activated on soil. Effective on mature primrose and wild radish. BY FAR the most effective option for emerged pigweed. If extended residual control is desired, consider adding Valor to the mixture but follow appropriate plant-back interval.	<i>paraquat</i> 2SL 3SL + <i>diuron</i> Direx 4F	22 + 7	2.5–4pt 1.7–2.7pt + 1.5–2pt	0.63–1 + 0.75–1	24 H/ N/A	EPA has restricted the use of <i>paraquat</i> to certified applicators ONLY and applicators must take a specialized training before use. A Section 24(c) Georgia Local Need Label allows Direx to be applied without a plant back interval as long as a strip-till rig with a ripper shank is run after application and before planting. If Direx is applied and a strip-till implement is not run then the plant back interval is 7 days. Other labeled <i>diuron</i> formulations require application 15–45 days ahead of planting. Label prohibits use on soils with less than 1% organic matter. Suggest to not apply another application of <i>diuron</i> or Cotoran within 21 days. Add crop oil concentrate at 1 gal/100-gal spray mix. Applications to mature weeds are much more effective than to immature weeds.

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

WEED	HERBICIDE	MOA	BROADCAST RATE/ACRE		REI/PHI (Hours or Days)	REMARKS AND PRECAUTIONS
			AMOUNT OF FORMULATION	LBS ACTIVE (AI or AE)		
PRE-PLANT INCORPORATED—ANY VARIETY						
Annual grasses, pigweeds and Florida pusley. Controls <i>glyphosate</i> -resistant Palmer amaranth much more effectively than when applied preemergence.	<i>pendimethalin</i> Prowl 3.3 EC Prowl H203.8 AS	3	1.2–2.4 pt 2 pt	0.5–1 0.95	24 H/ N/A	Soil incorporate to a depth of 2" in moist soil within 24 hours of application; consider mixing with Reflex. Application/incorporation within a week of planting is preferred.
	<i>trifluralin</i> Treflan, others 4 EC	3	1–2 pt	0.5–1	12 H/ N/A	<i>Pendimethalin</i> is less volatile than trifluralin thus is a better option if incorporation is delayed, delayed incorporation will reduce control. For Treflan 4 L, rate should not exceed 1.5 pt/A for most fields. The addition of a preemergence herbicide is critical in controlling Palmer amaranth.
<i>Glyphosate</i> -resistant Palmer amaranth and yellow nutsedge For PPO-resistance management, make only 3 applications of Valor or Reflex (including generics) on a field in 3 years.	<i>fomesafen</i> Reflex 2S	14	12–16 fl oz	0.19–0.25	24 H/ N/A	A Section 2 (ee) Georgia Label allowing this use has currently expired but is being renewed; confirm it is approved before using. The label allows a pre-plant application by incorporating Reflex to a 2" or less depth while the soil is moist; suggest including <i>pendimethalin</i> or <i>trifluralin</i> . The addition of a preemergence herbicide as noted with the split program below is critical; reduce Reflex rate accordingly if implementing split PPI and PRE program. For Palmer amaranth, less control is noted with Reflex alone incorporated when compared to preemergence applications if activated immediately by rainfall or irrigation; less injury potential is also noted with incorporated application. Thus, the split program below, is usually the best option.
SPLIT PROGRAM WITH PRE-PLANT INCORPORATED (PPI) FOLLOWED BY PRE-EMERGENCE (PRE) APPLICATIONS—ANY VARIETY						
The SINGLE MOST effective approach for the control of Palmer amaranth; especially in dryland production. For PPO-resistance management, make only 3 applications of Valor or Reflex (including generics) on a field in 3 years.	PPI:				24 H/ N/A	PPI: A Section 2 (ee) Georgia Label allowing this use has currently expired but is being renewed; confirm it is approved before using. Shallow (2") incorporation is required. Plant within 1 week of application and incorporation if possible. Numerous formulations of <i>fomesafen</i> are available; however, their labels may not support this use pattern.
	<i>trifluralin</i> or <i>pendimethalin</i> +	3 +	See rates in pre-plant incorporated +	See rates in pre-plant incorporated +		
	<i>fomesafen</i> Reflex 2S	14	10–12 fl oz	0.16– 0.19		
PRE:				24 H/ N/A	PRE: 1. Be sure to include <i>paraquat</i> PRE if Palmer is emerged. 2. Warrant offers greater residual control when compared to <i>diuron</i> while <i>diuron</i> offers greater control of emerged weeds. 3. If mixing Reflex + Warrant + Diuron, the rate of <i>diuron</i> for most fields should not exceed 10 oz/A. Numerous formulations of <i>fomesafen</i> and <i>diuron</i> are available.	
<i>fomesafen</i> Reflex 2S +	14 +	8–10 fl oz +	0.125–0.16 +			
<i>acetochlor</i> Warrant 3ME OR	15 OR	32 fl oz OR	0.75 OR			
<i>diuron</i> Direx, Diuron 4F	7	10–20 fl oz	0.31–0.63			

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

WEED	HERBICIDE	MOA	BROADCAST RATE/ACRE		REI/PHI (Hours or Days)	REMARKS AND PRECAUTIONS
			AMOUNT OF FORMULATION	LBS ACTIVE (AI or AE)		
PRE-EMERGENCE WEED CONTROL—ANY VARIETY						
Residual control of annual grasses, Palmer amaranth, and tropical spiderwort.	<i>acetochlor</i> Warrant 3ME	15	2–3 pt	0.75–1.125	12 H/ N/A	Warrant should be applied in combination with fomesafen (Reflex, others), <i>diuron</i> , Brake, or Cotoran depending on Palmer population and technology grown; add <i>paraquat</i> and adjuvant if Palmer is up. Apply within 24 hours of planting. The manufacturer recommends 3 pt/A; however, UGA research suggests a rate of 2 pt/A is in order when 1) tank mixing with another effective residual herbicide, 2) applying on light soil textures, and/or 3) using intense irrigation or expecting heavy rains during the first 2 weeks of planting.
Residual control of many annual grasses and broadleaves including Palmer amaranth and tropical spiderwort; suppression of yellow nutsedge.	<i>acetochlor</i> + <i>fomesafen</i> Warrant Ultra 3.45 CS	15 + 14	2.24 pt	0.77 + 0.175	24 H/ N/A	Apply within 24 hr of planting; add <i>paraquat</i> plus adjuvant if Palmer is up. Warrant Ultra at 2.24 pt/A provides 2 pt of Warrant and 0.175 lb ai of fomesafen (equivalent to 11 oz/A of Reflex). This rate is ideal for lighter soil textures, under intense irrigation, and when used in <i>dicamba</i> or 2,4-D-based programs. See label for manufacturer's higher use rate suggestions, if interested.
Residual suppression of annual broadleaf weeds and grasses. More effective than Cotoran on pigweed, less effective on most other weeds.	<i>diuron</i> Direx, others 80 DF Direx, others 4L	7	0.38–0.78 lb 10–20 fl oz	0.31–0.62	12 H/ N/A	<i>Diuron</i> should be applied in combination with fomesafen (Reflex, others), Warrant, or Brake depending on Palmer population and technology grown; add <i>paraquat</i> and adjuvant if Palmer is up. Apply within 24 hr of planting. See label for specific rate but in general use lower rate on sandier soils and/or under intense irrigation. Label restricts use on soils with < 1% organic matter. Suggest avoiding <i>diuron</i> PRE if applied burndown within 21 days of planting. Numerous generic formulations are available.
Residual suppression of annual broadleaf weeds and annual grasses. The most effective single residual material for sicklepod, cocklebur, and morning glory control. Less effective than <i>diuron</i> on Palmer amaranth.	<i>fluometuron</i> Cotoran 4F	7	2–3 pt	1–1.5	12 H/ N/A	Cotoran should be applied in combination with fomesafen (Reflex, others) or Warrant depending on Palmer population and technology grown; add <i>paraquat</i> and adjuvant if Palmer is up. Apply within 24 hr of planting. See label for specific rate on soils; in general use lower rate on sandier soils and/or with intense irrigation. A maximum of 2 pt/A is ideal for many GA soils.
Excellent residual control of Palmer amaranth once activated. New herbicide chemistry for most cotton growers.	<i>fluridone</i> Brake 1.2F	12	16–32 fl oz	0.15–0.3	48 H/ N/A	Tank mix Brake with another residual herbicide when using less than 21 oz/A. Data shows that if one does not mix Brake with another effective herbicide, Palmer amaranth will often emerge prior to Brake activation. Do not apply more than 2 years in a row in a field. Also study rotational restrictions on label; for rates of 16–21 oz/A carryover of 4 months for soybean, 8 months for wheat/rye/peanut, 12 months for corn/sorghum, and 18 months for sunflower, pepper, tomato, and tobacco is noted.

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

WEED	HERBICIDE	MOA	BROADCAST RATE/ACRE		REI/PHI (Hours or Days)	REMARKS AND PRECAUTIONS
			AMOUNT OF FORMULATION	LBS ACTIVE (AI or AE)		
PRE-EMERGENCE WEED CONTROL—ANY VARIETY <i>(continued)</i>						
Excellent residual for Palmer amaranth; good control of poinsettia and suppression of yellow nutsedge. For PPO resistance management, make only 3 applications of <i>fomesafen</i> or Valor (including generics) on a field in 3 years.	<i>fomesafen</i> Reflex, Dawn 2S	14	10–16 fl oz	0.16–0.25	24 H/ N/A	Reflex or generics should be applied in combination with Warrant, <i>Diuron</i> , Brake, or Cotoran depending on Palmer population and technology grown; add <i>paraquat</i> and adjuvant if Palmer is up. Apply within 24 hr of planting. Research suggests 12 oz/A is an appropriate rate when mixed with other effective residuals on most soils; lower rates on lighter, low organic-matter soil and/ or when using intense irrigation. Injury more often occurs when initial rains or irrigation occurs as cotton is emerging. Good residual pigweed control even if the first rain does not occur until 15 days after treatment; pigweed that emerges before activation will not be controlled. Reflex and Dawn have been tested intensely; other brands are available.
Annual grasses and Florida pusley; suppression of Palmer amaranth only. Irrigation or rainfall needed within 24 hours.	<i>pendimethalin</i> Prowl 3.3 EC Prowl H20 3.8 AS	3	1.8–3.6 pt 2–3 pt	0.75–1.5 0.95–1.42	24 H/ N/A	Preemergence applications are far less consistent than incorporated treatments; tank mixtures are needed. Wet/moist conditions during emergence (rainfall or irrigation) can cause significant plant stunting, leaf/ stem malformation, and stem swelling with eventual breaking; especially if used in combination with Reflex (or generic). Apply within 24 hours of planting.
Controls non-ALS resistant pigweeds, lambsquarters, prickly sida, spurge, and smartweed. Suppresses morning glory, except tall.	<i>pyrithiobac</i> Staple LX 3.2S	2	1.7–2.1 fl oz	0.0425–0.053	4 H/ N/A	Has excellent residual herbicide activity but cotton injury, especially on irrigated light textured soils, is a serious concern. Thus, a delayed PRE or early POST use of Staple is recommended. Do not apply on soils with less than 0.5% organic matter. Can tank mix with <i>diuron</i> , <i>fluometuron</i> , <i>pendimethalin</i> , or Reflex; apply within 24 hr of planting. Include <i>paraquat</i> or <i>glyphosate</i> if weeds are emerged.

			AMOUNT OF FORMULATION	LBS ACTIVE (AI or AE)		
POST-EMERGENCE OVERTOP WEED CONTROL—ANY VARIETY <i>(continued)</i>						
Non-ALS resistant pigweed less than 1", morningglory (excluding tall mg), coffee senna, and redweed. At most, suppresses sicklepod. Provides good residual control of many species if it reaches the ground and is activated.	<i>pyrithiobac</i> Staple LX 3.2S	2	2.7–3 fl oz	0.06–0.07	4H/ 60D	Apply overtop of cotton from cotyledonary stage up to 60 days of harvest. Avoid applying during periods of cool, wet weather. Include nonionic surfactant at 1 qt/100 gal spray mix. Label allows 2 applications per year, not exceeding a total of 5.1 fl oz. Label also allows increasing rate of an application to 3.8 fl oz but injury is a concern. Residual control of non-ALS resistant Palmer has been good even if the first activating rain does not occur for 15 days after application, plants emerging before activation will not be controlled. Do not mix with grass control herbicides. May mix with most insecticides, but do not tank mix with any product containing malathion. Do not mix with any Dual product or Warrant. Separate Staple and Dual/Warrant applications by 5 or more days. See label for rotational restrictions.
Annual broadleaf weeds including sicklepod, <i>Ipomoea</i> morningglory, and nutsedge. Will not control smallflower morningglory or ALS-resistant pigweed, jimsonweed, copperleaf, or prickly sida.	<i>trifloxysulfuron</i> Envoke 75WDG	2	0.1 oz	0.0047	12 H/ 60D	Sloppy directed application strongly encouraged for less injury and improved weed coverage in larger cotton. Label allows directed or overtop application after cotton has at least 6 (prefer 7) true leaves up until 60 days of harvest. Add nonionic surfactant at 1 qt/100 gal; do not use other types of adjuvants. Do not mix with other pesticides including plant growth regulators. In an attempt to avoid injury, do not apply to cotton under stress, such as very dry, wet, or cool conditions. Envoke may be directed to cotton 6" or larger at rates of 0.1–0.25 oz/A. See label for details and rotational restrictions. Rainfast in 3 hours. Provides some residual control of sensitive weeds if contacts soil and is activated.
Many broadleaf weeds. Poor control of tropic croton, copperleaf and ALS-resistant pigweed. Good residual of sensitive weeds if contacts soil and is activated.	<i>trifloxysulfuron</i> Envoke 75WDG + <i>pyrithiobac</i> Staple LX 3.2SL	2 + 2	0.1 oz + 1.3–1.9 fl oz	0.0047 + 0.03–0.05	12 H/ 60D	Sloppy directed application strongly encouraged for less injury and improved weed coverage on larger cotton. Label allows overtop or directed application after cotton has at least 6 (prefer 7) true leaves up until 60 days of harvest. Add nonionic surfactant at 1 qt/100 gal spray mix. See comments and restrictions for each product applied alone.

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

WEED	HERBICIDE	MOA	BROADCAST RATE/ACRE		REI/PHI (Hours or Days)	REMARKS AND PRECAUTIONS
			AMOUNT OF FORMULATION	LBS ACTIVE (AI or AE)		
POST-EMERGENCE OVERTOP WEED CONTROL—ENLIST, GLYTOL LIBERTYLINK, OR XTENDFLEX VARIETIES ONLY						
Control of pusley, spiderwort, and goosegrass are not consistent. In general, broadleaf weeds should be < 3" and grasses < 2". Excellent control of morningglory including moonflower. For Palmer amaranth, apply 29 oz/A when less than 3"; 32 oz/A when 3"; 36 oz/A when 4"; and 43 oz/A when taller than 4". Do not tank mix with grass herbicides. Suggest no more than 2 applications per year on a field; include two herbicides PRE, residual mixtures POST, and a directed layby.	<i>glufosinate</i> Liberty 2.34S	10	29–43 fl oz	0.53–0.79	12 H/ 70D	Enlist, Glytol LibertyLink, or XtendFlex variety Label allows application from emergence through early bloom; however, UGA recommends applications directed after 8 leaf cotton to minimize injury while improving weed control. Do not exceed 43 fl oz/A per application. Also, do not exceed 87 fl oz/A per season with individual applications of 29 fl oz/A or less, and do not exceed 72 oz/A per season if any individual application greater than 29 oz/A is made. A Section 24(c) Georgia Local Need Label allows two applications as close as 5 days apart when Liberty is applied alone; if using tank partners, the intervals should be at least 10 days. To maximize control: > 15 GPA water volume, thorough spray coverage, warm temperatures, high humidity, bright sunlight, good soil moisture, and do not spray within 1.5 hours of sunrise or 2 hours of sunset. Mixtures with residual herbicides are usually needed to assist in the control of grasses, pusley, spiderwort, and pigweed. Research has shown in some environments, especially saturated soils, injury from Liberty is greatest in XtendFlex cotton followed by Enlist cotton and least with Glytol LibertyLink cotton. Cheetah and Interline are formulations of glufosinate that have been tested; other brands are available. Rain fast within 4 hours.
Mixing <i>glyphosate</i> with Liberty will not influence control by Liberty; however, grass control will often be more than Liberty alone but less than that by <i>glyphosate</i> alone.	<i>glufosinate</i> Liberty 2.34S + <i>glyphosate</i> numerous brands	10 + 9	29–43 fl oz + see <i>glyphosate</i>	0.53–0.79 + 0.75–1.13 lb ae	12 H/ 70D	Enlist, Glytol LibertyLink, and XtendFlex variety See comments for <i>glufosinate</i> and <i>glyphosate</i> alone. Injury on Glytol LibertyLink is almost always negligible; injury on Enlist and XtendFlex is often increased slightly above <i>glufosinate</i> applied alone. Some leaf speckling/burn will likely occur. Injury may be enhanced if applied to cotton with dew, under extremely high temperatures, during times of saturated soils, or when mixed with insecticides or adjuvants.
Staple may improve emerged pigweed control (non ALS-resistant) and provides residual activity on sensitive weeds if spray contacts soil and is activated.	<i>glufosinate</i> Liberty 2.34S + <i>pyrithiobac</i> Staple LX3.2SL	10 + 2	29–43 fl oz + 1.9 fl oz	0.53–0.79 + 0.03–0.05	12 H/ 60D	Enlist, Glytol LibertyLink, or XtendFlex variety See information for <i>glufosinate</i> and <i>pyrithiobac</i> alone. Leaf speckling/burn/chlorosis will occur. Avoid dew, extremely high temperatures, saturated soils, and mixtures with other pesticides or adjuvants to reduce injury potential. Do not mix with any <i>metolachlor</i> (Dual) product or Warrant.

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

POST-EMERGENCE OVERTOP WEED CONTROL—ENLIST, GLYTOL LIBERTYLINK, OR XTENDFLEX VARIETIES ONLY <i>(continued)</i>						
Dual or Warrant provides residual control of grasses, spiderwort, and pigweeds if spray contacts soil and is activated. Outlook provides residual control of grasses and pigweeds; spiderwort has not been fully studied.	<i>glufosinate</i> Liberty 2.34S + <i>acetochlor</i> Warrant 3ME	10 + 15	29–43 fl oz + 2 pt	0.53–0.79 + 0.75	12 H/ 70D	Enlist, Glytol LibertyLink, or XtendFlex variety See information above or labels for <i>glufosinate</i> , <i>acetochlor</i> , <i>S-metolachlor</i> , and <i>dimethenamid</i> alone. Warrant mixture can be applied from fully emerged cotton through early bloom; label allows use rates up to 3 pt/A. Dual Magnum mixture can
	<i>glufosinate</i> Liberty 2.34S + <i>S-metolachlor</i> Dual Magnum 7.62 EC	10 + 15	29–43 fl oz + 1 pt	0.53–0.79 + 0.95	24 H/ 100 D	be applied from fully emerged cotton through 100 days before harvest if applied otop or 80 days before harvest if directed. Outlook mixture can be applied from 1-leaf cotton through second week of bloom. UGA research strongly encourages these mixtures to be directed after 8-leaf cotton for reduced injury and better weed control. Some leaf speckling/burn will likely occur. Injury may be enhanced if applied to cotton with dew, under extremely high temperatures, saturated soils, or when mixed with insecticides or adjuvants.
	<i>glufosinate</i> Liberty 2.34S + <i>dimethenamid-P</i> Outlook 6 EC	10 + 15	29–43 fl oz + 12–16 fl oz	0.53–0.79 + 0.56–0.75	12 H/ 70D	Several products containing <i>metolachlor</i> (not <i>S-metolachlor</i>) are available. <i>Metolachlor</i> products are less effective per unit of formulated product than those with <i>S-metolachlor</i> . In general, it takes 1.5 pt of a <i>metolachlor</i> product to give the activity one gets from 1 pt of <i>S-metolachlor</i> .
POST-EMERGENCE OVERTOP WEED CONTROL—ENLIST, GLYTOL LIBERTYLINK, ROUNDUP READY FLEX, OR XTENDFLEX VARIETIES						
Controls most annual weeds; exceptions include <i>glyphosate</i> -resistant Palmer amaranth, dayflower, Florida pusley, tropical spiderwort, doveweed, and hemp sesbania. Timely applications critical for purslane and morning glory.	<i>glyphosate</i> 4S (3 lb ae) 5.4S (4 lb ae) 5S (4.17 lb ae) 5.5S (4.5 lb ae) 5.88S (4.88 lb ae) 6S (5 lb ae)	9	32–48 fl oz 24–36 fl oz 23–34 fl oz 22–32 fl oz 21–30 fl oz 19–29 fl oz	0.75–1.12 (lb ae)	4H/ 7D	Roundup PowerMax 3 (4.88 lb ae) may be applied otop or directed to Roundup Ready Flex technology anytime from cotton emergence until 7 days prior to harvest. The maximum rate for any single application between emergence and 60% open bolls is 30 fl oz (1.13 lb ae). Do not exceed a total of 120 fl oz (4.5 lb ae) applied from emergence through 60% open bolls. Do not exceed a maximum of 40 fl oz (1.55 lb ae) applied between layby and 60% open bolls. Do not exceed a maximum of 40 fl oz between 60% open bolls and harvest. <i>Aglyphosate</i> -based program should include: 1) no weeds emerged at planting; 2) two residual herbicides at planting; 3) residual herbicides with Roundup POST and 4) a directed layby including conventional chemistry.

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

WEED	HERBICIDE	MOA	BROADCAST RATE/ACRE		REI/PHI (Hours or Days)	REMARKS AND PRECAUTIONS
			AMOUNT OF FORMULATION	LBS ACTIVE (AI or AE)		
POST-EMERGENCE OVERTOP WEED CONTROL—ENLIST, GLYTOL LIBERTYLINK, ROUNDUP READY FLEX, OR XTENDFLEX VARIETIES (<i>continued</i>)						
Warrant provides residual control of grasses, pigweeds, and tropical spiderwort, if it contacts the soil and is activated.	<i>glyphosate</i> + <i>acetochlor</i> Warrant 3ME	9 + 15	see <i>glyphosate</i> + 2 pts	0.75–1.12 + 0.075–1.125	12 H/ do not apply after 2 nd wk of bloom	See comments for <i>glyphosate</i> alone. Label allows a topical application once cotton is completely emerged until it reaches bloom; however, UGA research suggests making directed applications after the 8-leaf stage to reduce injury potential while improving weed control. A topical and directed application may be made as long as Warrant was not applied PRE; if Warrant was applied PRE then one POST application can be made. Label allows use rate up to 3 pt/A. Use loaded <i>glyphosate</i> formulation; do not add adjuvants or other pesticides including Staple. Avoid heavy dew on cotton plant, saturated soils, and extreme, hot conditions.
Outlook provides residual control of annual grasses and pigweeds if it reaches the soil and is activated; more data needed on spiderwort.	<i>glyphosate</i> + <i>dimethenamid-P</i> Outlook 6 EC	9 + 15	see <i>glyphosate</i> + 12–16 fl oz	0.75–1.12 + 0.56–0.75	12 H/ do not apply after 2 nd wk of bloom	See comments for <i>glyphosate</i> alone. Label allows a topical application from 1-leaf cotton through 2 nd week of bloom; however, UGA research suggests making directed applications after the 8-leaf stage to reduce injury potential while improving weed control. Only one application of Outlook per year. Suggested rate is 12 oz/A on coarse soils or under intense irrigation. Some leaf speckling/burn will likely occur. Avoid heavy dew on cotton plant, saturated soils, and extreme, hot conditions.
Staple improves control of hemp sesbania, morning glory, tropical spiderwort, and <i>glyphosate</i> -resistant Palmer amaranth. Staple will provide residual control of pigweeds, prickly sida, smartweed, spurred anoda, and velvetleaf if it contacts the soil and is activated. Will not control ALS+<i>glyphosate</i> resistant Palmer.	<i>glyphosate</i> + <i>pyrithiobac</i> Staple LX	9 + 2	see <i>glyphosate</i> + 2–3 fl oz	0.75–1.12 + 0.05–0.07	4 H/ 60D	See comments for <i>glyphosate</i> and Staple alone. Apply overtop from full cotton cotyledonary stage until 60 days prior to harvest. However, UGA research suggests making directed applications after the 8-leaf stage to reduce injury potential while improving weed control. Some leaf speckling/burn will likely occur. Avoid heavy dew on cotton plant, saturated soils, and extreme, hot conditions. Do not mix with any Dual/ <i>metolachlor</i> products or Warrant. For Palmer amaranth, apply Staple at 2.5–3 oz/A when Palmer is 2" or less; rate can be increased to 3.8 oz/A but injury is a concern. For residual control, a rate of 1.9–2.1 oz/A should perform very well.

			AMOUNT OF FORMULATION	LBS ACTIVE (AI or AE)		
POST-EMERGENCE DIRECTED—ANY VARIETY						
Control of many broadleaf weeds and nutsedge; residual control of many weeds if activated. If grasses are present, a <i>glyphosate</i> mixture would be in order. Grasses should be < 1". Diuron plus MSMA is the best directed option to control emerged <i>glyphosate</i>-resistant Palmer amaranth. <i>Diuron</i> is better on emerged pigweed than Cotoran or Valor. Valor provides more effective residual control of pigweed.	<i>diuron</i> Direx, Diuron, other 4F + <i>MSMA</i> (several brands) 6 lb/gal 6.6 lb/gal	7 + 17	1.6–2.4 pt + 2 pt 2 pt	0.8–1.2 + 1.5–1.65	12 H/ 1st Bloom	Apply as directed spray to cotton at least 12" tall. Addition of crop oil concentrate is strongly encouraged. Label prohibits use on sand or loamy sand soils, or any soils with less than 1% organic matter. If soil type allows, use at least 2 pt/A of <i>diuron</i> for control of emerged Palmer amaranth. Label prohibits applying <i>MSMA</i> after 1st bloom. To improve emerged morningglory control consider adding Envoke at 0.1 oz/A which has no additional injury concern. To improve spiderwort and grass residual control consider adding: 1) Dual Magnum 1 pt/A; or 2) Warrant 2–3 pt/A; or 3) Zidua 0.75–1.5 oz/A as long as cotton has at least 7 leaves; or 4) Outlook 12–16 fl oz/A Numerous formulations of <i>diuron</i> and <i>MSMA</i> are available.
Controls many broadleaf weeds and nutsedge; grasses should be < 0.5". Palmer amaranth should be < 2". Residual control of many weeds if activated. If grasses are present, a <i>glyphosate</i> mixture would be in order. <i>Diuron</i> is better on emerged pigweed than Cotoran or <i>flumioxazin</i> ; <i>flumioxazin</i> provides the best residual control by far.	<i>flumioxazin</i> Valor SX 51WDG Valor EZ 4 SC + <i>MSMA</i> (several brands) 6 lb/gal 6.6 lb/gal	14 + 17	2 oz 2 fl oz + 2.67 pt 2.5 pt	0.064 + 2	12 H/ 1st Bloom	Apply as a directed spray to cotton at least 18" tall. Apply to the lower 2" of the cotton stem and do not contact the green portion of the cotton stem. May apply to 6" cotton under a hood with no crop contact. Add nonionic surfactant at 1 qt/100-gal spray mix. DO NOT use crop oil concentrate, methylated seed oil, organo-silicone adjuvant, or any adjuvant containing any of these. Label prohibits applying <i>MSMA</i> after 1st bloom. IN HOODED APPLICATIONS when no crop contact occurs; the addition of Dual or Warrant is recommended for managing tropical spiderwort and Palmer amaranth. Outflank, Panther, and Rowel perform similarly to Valor. For PPO-resistance management, make only 3 applications of Valor or Reflex (including generics) on a field in 3 years.
The single best layby mixture for control of both emerged <i>glyphosate</i> -resistant Palmer amaranth and extended residual control. Grass must be < 0.5". Be careful, mixture is "hot."	<i>flumioxazin</i> Valor SX 51WDG Valor EZ 4 SC + <i>diuron</i> Direx, others 4F + <i>MSMA</i> (several brands) 6 lb/gal 6.6 lb/gal	14 + 7 + 17	2 oz 2 fl oz + 1 pt + 2 pt 2 pt	0.064 + + 0.5 + 1.5 1.65	12 H/ 1st Bloom	Cotton should be at least 20" tall. Apply as a directed spray to the lower 2" of the barked portion of the cotton stem. Do not contact any green portion of the stem. Experiment with this mixture on limited acreage as crop injury is of some concern. Add nonionic surfactant at 1 qt/100-gal spray mix. DO NOT use crop oil concentrate, methylated seed oil, organo-silicone adjuvant, or any adjuvant containing any of these. Label prohibits applying <i>MSMA</i> after 1st bloom.

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

			AMOUNT OF FORMULATION	LBS ACTIVE (AI or AE)		
POST-EMERGENCE DIRECTED—ANY VARIETY <i>(continued)</i>						
Effective control of many broadleaf weeds and nutsedge; grasses should be <0.5" and Palmer <2". Will not improve control of emerged weeds compared to <i>flumioxazin</i> + <i>MSMA</i> but better residual control is likely.	<i>flumioxazin</i> + <i>pyroxasulfone</i> Fierce 76 WDG Fierce EZ3.04SC + <i>MSMA</i> 6lb/gal 6.6 lb/gal	14+15 + 17	3 oz 6 fl oz + 2.67 pt 2.5 pt	0.063+0.08 + 2	12 H/ 1st Bloom	Apply as a directed spray to cotton at least 18" tall. Direct spray to the lower 2" of a barky cotton stem; do not contact the green portion of the cotton stem. May apply to 6" cotton under a hood as long as no crop contact. Add nonionic surfactant at 1 qt/100 gal spray mix. DO NOT use crop oil concentrate, methylated seed oil, organo-silicone adjuvant, or any adjuvant containing any of these. Label prohibits applying <i>MSMA</i> after 1st bloom.
Effective control of many broadleaf weeds, nutsedge, and small annual grasses. Residual control of many weeds. Less effective than <i>diuron</i> mix for emerged pigweed and less residual on pigweed than <i>diuron</i> or Valor.	<i>fluometuron</i> Cotoran 4F + <i>MSMA</i> (several brands) 6 lb/gal 6.6 lb/gal	7 + 17	2–3.2 pt + 2.67 pt 2.5 pt	1–1.6 + 2	12 H/ 1st Bloom	Apply as a directed spray to cotton at least 3" tall; cotton has very good tolerance. Label prohibits applying <i>MSMA</i> after 1st bloom. The addition of Envoke at 0.1 oz/A will improve morning glory control and can be added as long as cotton has at least 6" tall. The addition of a Dual type product or Warrant is recommended for managing tropical spiderwort and Palmer amaranth.
Effective control of many broadleaf weeds, nutsedge, and small annual grasses. Less effective than <i>diuron</i> mix in controlling emerged pigweed and less residual on pigweed than <i>diuron</i> or Valor.	<i>prometryn</i> Caparol 4F + <i>MSMA</i> (several brands) 6 lb/gal 6.6 lb/gal	5 + 17	1.3–2.4 pt + 2.67 pt 2.5 pt	0.65–1.2 + 2	12 H/ 1st Bloom	Apply as a directed spray. Use 1.3 pt/A Caparol in 8–12" cotton and up to 2.4 pt/A in cotton at least 12". Add nonionic surfactant at 2 qt/100-gal spray solution. Label prohibits applying after 1st bloom. The addition of Envoke at 0.1 oz/A will improve morning glory control. The addition of a Dual-type product or Warrant is recommended for managing tropical spiderwort and Palmer amaranth.
POST-EMERGENCE DIRECTED—ENLIST, GLYTOL LIBERTY LINK, ROUNDUP READY FLEX, OR XTENDFLEX VARIETIES						
Controls most annual weeds; exceptions include resistant Palmer amaranth, dayflower, doveweed, Florida pusley, tropical spiderwort, and hemp sesbania. Morning glory and purslane can be challenging.	<i>glyphosate</i> 4S (3 lb ae) 5.4S (4 lb ae) 5S (4.17 lb ae) 5.5S (4.5 lb ae) 5.88S (4.8 lb ae) 6S (5 lb ae)	9	32–48 fl oz 24–36 fl oz 23–34 fl oz 22–32 fl oz 21–30 fl oz 19–29 fl oz	0.75–1.12 lb ae	4 H/ 7D	<i>Glyphosate</i> should almost never be applied alone. Label allows directed application up to 7 days prior to harvest. Improved weed coverage with a directed application generally occurs after 8-leaf cotton. <i>Aglyphosate</i> -based program should include: 1) no weeds emerged at planting; 2) two residual herbicides at planting; 3) residual herbicides with Roundup POST; and 4) a directed layby including conventional chemistry.
Mixing <i>diuron</i> with <i>glyphosate</i> improves morning glory and Palmer amaranth control; although morning glory control may still not be acceptable. Also provides residual control of some broadleaf weeds, such as pigweed. The tank mix may give less grass control than <i>glyphosate</i> alone.	<i>glyphosate</i> + <i>diuron</i> Direx, <i>Diuron</i> 4F	9 + 7	see <i>glyphosate</i> + 1-1.5 pt	0.75–1.12 + 0.5–0.75	12 H/ 7D	Use 1 pt/A of <i>diuron</i> on cotton 8–12" and up to 1.5 pt/A of <i>diuron</i> on cotton greater than 12". To improve spiderwort, pigweed, and grass residual control consider adding: 1) Dual Magnum 1 pt/A; 2) Warrant 2 pt/A; 3) Zidua 0.75–1.5 oz/A as long as cotton has at least 7 leaves; or 4) Outlook 12–16 oz/A. To improve morning glory control consider adding: 1) Envoke 0.1 oz/A, no additional restrictions; or 2) Valor 1–1.5 oz/A, cotton should be at least 18" tall with spray contacting only bottom 2" of barky stem. Residual Palmer control by <i>diuron</i> at this rate often lasts 7–10 days.

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

POST-EMERGENCE DIRECTED—ENLIST, GLYTOL LIBERTY LINK, ROUNDUP READY FLEX, OR XTENDFLEX VARIETIES (<i>continued</i>)						
Mixing Valor with <i>glyphosate</i> improves morningglory and tropical spiderwort control and provides residual control of many broadleaf weeds including pigweeds, purslane, and Florida pusley. Often poor control of <i>glyphosate</i> -resistant Palmer amaranth over 1" but excellent residual control.	<i>glyphosate</i> + <i>flumioxazin</i> Valor SX 51WDG Valor EZ4SC	9 + 14	see <i>glyphosate</i> + 1–2 oz 1–2 fl oz	0.75–1.12 + 0.031– 0.063	12 H/ 60D	Cotton should be at least 18". Direct spray to the lower 2" of barky cotton stem. Do not allow spray to contact green portion of stem. The addition of <i>diuron</i> will improve control of emerged pigweed. Add nonionic surfactant at 1 qt/100-gal spray mix but only if <i>glyphosate</i> brand requires adjuvant. DO NOT use crop oil concentrate, methylated seed oil, organo-silicone adjuvants, or any adjuvant product containing these. Outflank, Panther, and Rowel perform similarly to Valor. For PPO-resistance management , make only 3 applications of Valor or Reflex (including generics) on a field in 3 years.
Provides similar post-emergence control as <i>glyphosate</i> + Valor but provides greater residual control for many weeds including spiderwort and Palmer amaranth.	<i>glyphosate</i> + <i>flumioxazin</i> + <i>pyroxasulfone</i> Fierce 76 WDG Fierce EZ3.04 SC	9 + 14+15	see <i>glyphosate</i> + 3 oz 6 fl oz	0.75–1.12 +0.063 +0.08	12 H/ 60D	Cotton should be at least 18" tall. Direct spray to the lower 2" of a barky cotton stem; do not contact the green portion of the cotton stem. May apply to 6" cotton under a hood as long as no crop contact. Add nonionic surfactant according to the Fierce label. DO NOT use crop oil concentrate, methylated seed oil, organosilicone adjuvant, or any adjuvant containing any of these.
Mixing Caparol with <i>glyphosate</i> improves morningglory control and provides residual control of sensitive species; although morningglory must still be small for adequate control. The tank mix may give less grass control than <i>glyphosate</i> alone.	<i>glyphosate</i> + <i>prometryn</i> Caparol 4F	9 + 5	see <i>glyphosate</i> + 1–2 pt	0.75–1.12 + 0.5–1	12 H/ —	Cotton should be at least 8" for Caparol rate between 1–1.3 pt and at least 12" for Caparol rate above 1.3 pt. Add surfactant but only if <i>glyphosate</i> brand requires it. To improve spiderwort, pigweed, and grass residual control consider adding: 1) Dual Magnum 1 pt/A; 2) Warrant 2 pt/A; 3) Zidua 0.75–1.5 oz/A as long as cotton has at least 7-leaf; or 4) Outlook 12–16 oz/A. To improve morningglory control consider adding: 1) Envoke 0.1 oz/A, no additional restrictions; or 2) Valor 1–1.5 oz/A, cotton should be at least 18" tall with spray contacting only bottom 2" of barky stem. Occasionally, directed applications to succulent cotton stems cause chlorosis from <i>prometryn</i> throughout the plant.
Mixing Anthem Flex with <i>glyphosate</i> will improve control of morningglory and spiderwort while providing residual control of sensitive species.	<i>glyphosate</i> + <i>pyoxasulfone</i> + <i>carfentrazone</i> Anthem Flex 4SL	9 + 15+14	see <i>glyphosate</i> + 1.36–2.7 fl oz	0.75–1.12 + 0.04+0.003–0.079+0.006	12 H/ 7D	Suggest cotton at least 18 inches (label allows application as long as cotton is over 12 inches; see label). Direct spray to the lower 2" of a barky cotton stem; do not contact the green portion of the cotton stem, foliage, or blooms. Limited UGA research, gain experience before significant use.
Mixing Envoke with <i>glyphosate</i> improves <i>Ipomoea</i> morningglory and nutsedge control and provides some residual control of sensitive species.	<i>glyphosate</i> + <i>trifloxysulfuron</i> Envoke 75WDG	9 + 2	see <i>glyphosate</i> + 0.1–0.2 oz	0.75–1.12 + 0.005– 0.009	12 H/ 60D	Direct to cotton from 6" tall through layby; minimize contact on small cotton. Add nonionic surfactant according to Envoke label. Excellent tolerance when directed. The addition of <i>diuron</i> will improve control of emerged pigweed.

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

WEED	HERBICIDE	MOA	BROADCAST RATE/ACRE		REI/PHI (Hours or Days)	REMARKS AND PRECAUTIONS
			AMOUNT OF FORMULATION	LBS ACTIVE (AI or AE)		
ADDITIONAL POST-EMERGENCE DIRECTED—XTENDFLEX VARIETIES ONLY						
<p><i>Dicamba</i> can be extremely effective on many broadleaf weeds but tank mixtures are needed for effective control.</p> <p>Tavium includes <i>S-metolachlor</i> and will provide excellent residual control of many weed species, if activated, such as spiderwort, pigweeds, and some grasses.</p>	<p><i>dicamba</i> XtendiMax 2.9S</p>	4	—	—	24H/ see remarks	<p><i>Dicamba</i> Tolerant Varieties Only. XtendiMax and Tavium labels are expected to change for 2022, refer to the most recent labels for use requirements and restrictions.</p> <p>State labels allowing XtendiMax and Tavium to be applied as directed sprays to tolerant cotton have been cancelled; current efforts to obtain these labels again are in progress. Contact your extension agent for details.</p>
	<p><i>dicamba</i> + <i>S-metolachlor</i> Tavium</p>	4 + 15	—	—		
POST-EMERGENCE—HOODED ROW MIDDLE—ANY CULTIVAR						
<p><i>Glyphosate</i> as a hooded application is especially effective for prostrate, running species such as citron, burgherkin, and annual grasses.</p> <p>SUGGEST NOT USING LIQUID NITROGEN AS ENTIRE CARRIER.</p>	<p><i>glyphosate</i> 4S (3 lb ae) 5.4S (4 lb ae) 5S (4.17 lb ae) 5.5S (4.5 lb ae) 6S (5 lb ae)</p>	9	<p>32–48 fl oz 24–36 fl oz 23–34 fl oz 22–32 fl oz 19–29 fl oz</p>	0.75–1.12	4H/ 7D	<p>In varieties not resistant to <i>glyphosate</i>, hoods should be kept as close to the ground as possible preventing spray from contacting stems or foliage. Apply in 5–10 GPA at a maximum of 25 PSI. Do not exceed 5 MPH. Suggest that cotton be at least 8" tall.</p> <p>Other herbicides such as Aim, Caparol, Diuron, Dual Magnum, Envoke, ET, Fierce, Staple, Valor, Warrant or Zidua should be mixed with <i>glyphosate</i> to improve weed control. Follow application restrictions as provided on labels.</p>
<p>Annual grass and broadleaf weeds; suppression of nutsedge.</p> <p>Mixtures with <i>diuron</i> would be the most effective option to control emerged pigweed in row middles.</p>	<p><i>paraquat</i> 2SL 3SL</p>	22	<p>19–38 fl oz 0.8–1.3 pt</p>	0.3–0.6	24 H/ 3 D	<p>SALVAGE APPLICATION! DO NOT CONTACT COTTON STEMS OR FOLIAGE. EPA has restricted the use of <i>paraquat</i> to certified applicators ONLY and applicators must take a specialized training before use. Apply in a minimum of 10 GPA at a maximum of 25 PSI. Do not exceed 5 MPH. Hoods should be kept on the ground. Cotton should be at least 8". Add nonionic surfactant at 2pt/100 gal of spray mix or crop oil concentrate at 1 gal/100-gal spray mix.</p> <p>Caparol, Cotoran, or <i>diuron</i> (Direx, Diuron) mixed with <i>paraquat</i> will likely improve control of emerged weeds and provide residual control.</p> <p>If <i>paraquat</i> contacts the cotton stem severe damage is to be expected!</p>
<p>Timing for pigweed and grasses are critical. Control of pusley, spiderwort, and goosegrass is often not good. Generally, treat broadleaf weeds prior to 3" and grasses prior to 2".</p> <p>Excellent control of morning glory including moonflower morning glory.</p> <p><i>Diuron</i> plus <i>MSMA</i> is more effective on Palmer.</p>	<p><i>glufosinate-ammonium</i> Liberty 2.34S</p>	10	29–43 fl oz	0.53–0.79	12 H/ 70D	<p>On non-<i>glufosinate</i> tolerant cotton, keep hoods close to ground to avoid contact with cotton stem. Suggest cotton be at least 8". The addition of <i>diuron</i> or other residual herbicide strongly encouraged. Adjuvant not needed.</p> <p>To maximize control: ≥15 GPA water volume, thorough spray coverage, warm temperatures, high humidity, bright sunlight, good soil moisture, and do not spray within 1.5 hours of sunrise or 2 hours of sunset.</p> <p>Numerous other brands of <i>glufosinate</i> are available.</p> <p>Make no more than 2 applications of Liberty in a field per year.</p>

1. Mode of Action (MOA) code can be used to delay weed resistance by increasing herbicide diversity in a management program.

Key:

E—90% or better control
G—80–90% control
F—60–80% control
P—30–60% control
N—<30% control

Note: Ratings based on average to good soil and weather conditions for herbicide performance and on proper application rate, technique, and timing

1. Application rates per acre: Clarity (*dicamba*): 0.5 pt; 2,4-D: 1 pt; Aim: 1 oz; ET: 1–2 oz; diuron: 0.5–1.0 lb ai; glyphosate: 1.12 lb ae; paraquat: 0.75–1.0 lb ai; Harmony Extra TotalSol: 0.75 oz; Valor: 2 oz.
2. Mixing herbicides with *glyphosate* occasionally reduces grass control (including cover crops). This is more likely with large weeds in dry conditions.
3. Apply 2,4-D at least 30 days ahead of planting, except for varieties with the Enlist trait where planting can occur any time after application.
4. Following application of *dicamba* and a minimum of 1" of rainfall, a minimum 21-day waiting period before planting is required, except for varieties with the XtendFlex trait where planting can occur any time after an Engenia or XtendiMax application.
5. Harmony Extra should be applied at least 14 days prior to planting.
6. See plant-back restrictions noted in the previous section or on the label for Valor.
7. See previous cotton section on state label for reduced plant back interval for Direx.
8. This level of control requires plants to be in full bloom with seed forming when treated.
9. This level of control requires 2 pt of 2,4-D (3.8 lb ai per gallon product).
10. *Glyphosate* will not control *glyphosate-resistant* horseweed, see previous section on controlling this weed.
11. Small grain must have visible seedheads for this level of control.

VARIETY SELECTION

Choosing which variety to plant is one of the most critical steps in producing a cotton crop and achieving optimal yields and fiber quality. Currently, producers not only choose a variety based on genetic performance or yield potential, but also according to pest management traits or technology packages. There are many technology systems and packages that will be available in 2022. The predominant technology systems that will be available in 2022 include (but aren't necessarily limited to) conventional, Bollgard II Roundup Ready Flex (B2RF), Widestrike Roundup Ready Flex (WRF), Glytol Liberty Link TwinLink (GLT) Bollgard II Xtendflex (B2XF) and Widestrike 3 Enlist (W3FE). In variety "names" there is a set of letters after the name which designate technologies (See table below). For example, DP 1646 B2XF is a variety which has the Bollgard II Xtendflex technologies and therefore has a two-gene bt trait and herbicide tolerance to glyphosate, glufosinate and dicamba. It is generally advised that growers should strongly consider spreading their risks by planting multiple varieties. A single dominant variety is unlikely, however official variety trials and on-farm county variety trials have illustrated that several varieties can perform well in several environments. Considerations for variety selection should also be catered to a range of planting dates, seedling vigor, water regimes (irrigated versus dryland and degree/efficiency of irrigation), maturity classes, and plant growth characteristics, with the understanding that some varieties may perform better in certain situations than others.

Guide to Abbreviations for Cotton Technologies in Variety Nomenclature*

Abbreviation	Trait Name	Description
W	Widestrike	Two-gene insect trait (Cry1Ac + Cry1F)
W3	Widestrike III	Three-gene insect trait (Cry1Ac + Cry1F + Vip3A)
FE	Enlist	2,4-D Tolerant**, Glyphosate Tolerant, Glufosinate Tolerant
T	TwinLink	Two-gene insect trait (Cry1Ac + Cry2Ae)
TP	TwinLink Plus	Three-gene insect trait (Cry1Ac + Cry2Ae + Vip3A)
GL	Glytol Liberty Link	Glyphosate Tolerant, Glufosinate Tolerant
B2	Bollgard II	Two-gene insect trait (Cry1Ac + Cry2Ab)
B3	Bollgard III	Three-gene insect trait (Cry1Ac + Cry2Ab + Vip3A)
RF	Roundup Ready Flex	Glyphosate Tolerant
XF	XtendFlex	Dicamba Tolerant**, Glyphosate Tolerant, Glufosinate Tolerant

*This table is only meant to serve as a guide to help determine traits associated with particular varieties, in all cases contact industry representatives for more information and details on managing cotton with these traits.

**Contact Industry Representative for specific recommendations on herbicides and traits.

The average lifespan of cotton varieties is becoming significantly shorter, therefore growers have little time to gain experience with these varieties. Growers must therefore adapt quickly to new varieties and gain as much experience with them as possible within a short time frame. Variety selection at the grower level should be based on research data and local field experience. Attention should be given to both yield and fiber quality. Sources of data include trials from university experiment stations and county demonstration plots, seed company trials, and consultant trials. Results of the UGA On-Farm Cotton Variety Performance Evaluation Program are published on the UGA Cotton Web page at www.ugacotton.com. Small-plot UGA Official Variety Trial (OVT) data is also available at www.ugacotton.com as well as <http://www.swvt.uga.edu/>. It is very important to observe multi-year and multi-location data when possible, as well as fiber quality characteristics of these varieties, which can also be found at www.ugacotton.com. It is even more important to look for varieties that perform consistently well across locations of a similar environment (irrigated vs. dryland). Some varieties may perform well at a particular location

within a year; however, their average performance across similar environments may be much less, which may be an indicator of inconsistency or poor stability. Varieties that perform well across a wide range of environments indicate a high degree of stability, which in turn suggests that these varieties may result in good performance across planting dates, soil types, rainfall patterns and irrigation practices, grower management practices, and other factors. Results from at least two years and several locations often provide a better indication of anticipated performance and stability. Generally, the more years and locations the better, and while data are helpful, grower experience on the farm is the ultimate test. In addition, the adage, “Try a little, not a lot,” is still the preferred approach when implementing new technologies, varieties, and production practices on the farm, if possible. Contact your local UGA County Extension agent for the most up-to-date information on variety performance and selection.

PLANTING DATES

Long term research has shown little yield difference in planting dates between April 1 and May 25. However, the “best” planting window varies yearly. Early planting while moisture persists increases the likelihood of successful planting in non-irrigated fields. However, early planting comes with risks, including possible seedling vigor and disease problems associated with cool and/or wet periods, premature cutout related to the coincidence of early fruiting and drought, and late season boll rot due to expected rains in late August or early September. Boll rot is frequent in areas in which boll opening coincides with rainfall, high humidity, and overcast conditions. Seed sprouting from the exposed seedcotton can also be a problem during the fall of some years if similar conditions prevail. In addition to these problems, significant yield loss and quality degradation can occur when lint is exposed to rainfall and wind. Therefore, producers are encouraged to consider spreading risks by utilizing a range of planting dates each year.

Soil temperature is an important consideration for early planting. Generally, planting can safely proceed when the 4-inch soil temperatures reach 65° F for 3 days and warming conditions are projected over the next several days (or approximately 50 DD-60’s within 5 days of planting). Experience suggests that this is a very safe, conservative approach. For optimal emergence, soil temperatures should be 65° F or more during the first 2 to 3 days after planting into moist soil, as imbibed seed are often killed by temperatures of 41° F or below. Cotton seeds and seedlings are most sensitive to cool or cold temperatures during this time frame. Warm temperatures should also be likely within 5 days of planting, as temperatures below 50° F can cause chilling injury to emerging seedlings.

Delaying planting until late April and early May has shown advantages in deep South Georgia. Irrigated cotton should usually be planted after May 1, since the risk of having adequate moisture for getting a stand is eliminated, the possibility of boll rot from August rains is reduced, and thrips pressure is lessened. Also, boll opening and harvest-time rainfall risks are reduced and harvest can be accomplished from late September through November, normally our most likely rain-free period.

Many South Georgia producers grow both cotton and peanuts. The occurrence of tomato spotted wilt virus (TSWV) has resulted in a shift in peanut planting to mid-May and has also delayed the initiation of peanut harvest to mid-September. Competition for labor at harvest has often forced South Georgia producers to choose between the two crops, most often with cotton harvest being delayed. There is the possibility that early plantings (early to mid-April) and proper management

of short season cotton varieties under irrigation may allow harvest prior to peanut maturity. Early planting and subsequent early harvest may also be an avenue to enhance crop quality, as one of the major factors influencing overall crop quality is delayed defoliation and harvest. Potential benefits of this concept depends on favorable weather in early September, but planting a portion of the total crop helps “spread the risk.” In some years, cotton that matures and opens in late August or early September is subjected to severe boll rot. In addition, unfavorable weather at boll opening may in fact undermine the attempt to capture quality with early planting of shorter season varieties. Thus, planting a major portion of ones crop in this way is not advised. The adoption of on-board module building pickers may allow growers to harvest peanuts and cotton simultaneously, to the mutual benefit of both crops.

Weather prediction is an important part of agriculture. Ideally, an accurate understanding of future weather could guide planting so that fruiting coincides with abundant rainfall and that boll opening/harvest coincide with relatively rain-free periods. Unfortunately, neither accurate prediction nor control of weather exists. Season-long weather--particularly rainfall--continues to be the single greatest factor influencing yield.

Planting cotton at the end of May and during early-June can prove to be successful, yet there are significant risks that are associated with later plantings. It should be noted that with regard to planting dates, long-term observations have shown that reaching maximum yield potential is much more predictable with planting dates prior to the end of May than compared to later dates. The primary issue is related to maturation of the crop in a timely manner (or reaching full maturation prior to cool temperatures in the fall). With later planting dates, any delay in maturation may ultimately result in reduced yield potential and the “room for error” is considerably smaller. Irrigation can reduce some of the risk, due to the ability to ensure quick germination and stand establishment as well as reducing maturity delays associated with episodic drought which often occur during the growing season in Georgia. Another considerable issue with planting in late-May and early-June is centered on replanting. Although replanting is not something we expect to do, each year, especially in dryland situations, there are fields which need to be replanted for one reason or another. Planting the crop for the first time late in the planting window limits if not eliminates the opportunity to replant and maintain maximum yield potential. Planting the crop for the first time in April or early-May allows for adequate time to replant if necessary.

Overall, we are fortunate in Georgia to have such a wide window to plant cotton and be successful. Producers should make plans to take advantage of this by spreading risks by planting their crop over a range of dates. Spreading out planting dates limits the impact of episodic drought events, boll rot conditions, thrips injury at planting, seedling disease, etc. from taking a toll on the entire crop. Spreading planting dates can to some degree help with timely harvest, which can affect overall lint yields and will more than likely improve fiber quality. Be sure to contact your local UGA County Extension Agent for more information on optimum planting dates (especially for information surrounding the annual impact of planting dates and thrips management).

Double Crop or Late-Planted Cotton

Double-crop or "June" cotton is feasible in the Coastal Plain, especially in lower South Georgia where the growing season is longer. Early, cool fall weather delays maturity and limits yield in some years, but cotton planted in early June generally has adequate yield potential under intensive management, especially with irrigation. Some UGA research shows a possible yield reduction of up to 30 percent when comparing full-season cotton planted in early May to June planted cotton

after wheat harvest. Grower experience indicates increasing risk past the first week of June. The obvious limitation is an early frost or at least cool temperatures in mid to late October which inhibit boll maturation. In addition, because of the brevity of the potential fruiting period, timely rain or irrigation is absolutely necessary. Growers should be aware of crop insurance specifications related to late or double-crop cotton. Research studies along with grower experience indicate the following precautions or adjustments should be made when planting either as a double-crop after small grains or extremely late (near or after June 1):

Irrigation is strongly recommended to ensure a vigorous stand, rapid stand establishment, and boll retention during the normally dry period in late May and early June. Likewise, dry weather is expected after mid-August and before boll maturity is completed.

Management (PGRs, Fertility, Irrigation etc.) for a shorter season crop to maximize boll set and retention during the first 3 to 4 weeks of bloom.

Plant only 2 to 3 good quality seed/ft of row to alleviate the complications of late plantings and dense stands. SEE SECTION ON PLANT POPULATIONS / SEEDING RATES

Protect the terminal bud from injury by thrips or worms. Generally, thrips pressure is less in late May and early June plantings as compared to April to mid-May planting dates. Also, prevent plant bug and stink bug damage to avoid delays in fruiting.

Avoid crop injury by over-the-top sprays or other misuse of herbicides to prevent stress and delayed maturity.

Prevent fruit shed and fruiting gaps by good insect control, balanced nutrition, and irrigation.

Don't try to rush the crop by over fertilizing with N. Use minimum soil applied rates (usually 25 to 30 percent less than on full season) and monitor nitrate levels with petiole tests to detect need for late sidedness or foliar N application. P and K could be applied to the previous crop, except for sandy land, to save time especially if a starter is used to give N for early season growth.

Monitor the crop closely by plant mapping, square retention counts, etc., so that problems can be diagnosed and corrected to prevent further delays in maturity.

Use mepiquat-containing plant growth regulators if needed to prevent excess vegetative growth and boll rot, and to promote earliness.

Use ethephon (Prep, Finish, First Pick, etc.) harvest aid to promote boll opening, allow earlier harvest, and avoid freeze damage.

PLANT POPULATIONS / SEEDING RATES

Because the “per acre” technology costs of transgenic varieties are directly linked to seeding rates, growers are often tempted to minimize the number of seed/ft. In research trials conducted from 1995 to 1997, rates as low as 2 seed/ft resulted in plant stands ranging from 1.2 to 1.9 plants/ft and maximum lint yield over the 3-year study. Practically, a target of 2.5 seed/ft is a reasonable trade-off for economizing with expensive transgenic cotton. In a hill-drop planting system, which is often used to overcome the adverse effects of soil crusting, this seeding rate would be equivalent to 2 seed every 8 to 10 inches. Reducing seeding rates below 2.5 seed/ft often increases the chance of poor stand establishment and adverse effects on plant canopy structure or architecture, especially if environmental conditions are not suitable for rapid stand establishment. Skippy stands can reduce yields, delay maturity, and allow sunlight penetration through the canopy to be utilized by weeds.

Recent work has demonstrated that producers should aim for plant populations of at least 1.5 to

1.75 plants per row-foot to achieve maximum yields. This work, conducted during 2013 to 2016, examined seeding rates and plant populations in current production systems and varieties in high yield situations. Therefore, to ensure maximized yields with regards to seeding rates, producers should consider appropriate seeding rates to ultimately end up with the above mentioned 1.5 to 1.75 plants per row-foot. This presents a situation where producers should consider what practices and environmental circumstances impact germination and viability. Many things may impact results and in order to reach these stands, a seeding rate of at least 2 seed per row-foot is needed, and often much higher. Further work is being conducted to more adequately examine germination and viability in production systems and therefore more information will be coming soon.

One question often asked when considering seeding rates and plant populations is “should I plant with a hill-drop plate or plant seed evenly apart with one seed per hill”. A couple of things to consider when making this decision. First, research studies conducted during 2017 and 2018 has shown that when the same populations are achieved in both situations there is not statistical difference in yield. For example, the seeding rate of 30,000 seed per acre planted with seed evenly spaced apart and in two seed hills should yield similarly. The trick is what germination is achieved with the two systems. Hill-drop seeding may increase germination and ultimately impact yield from a standpoint of higher plant population than what would have emerged with single seed planting. Therefore, if hill-dropping seed helps with emergence, then it would likely be the better choice, if no advantage is provided with hill-dropping seed then either system would be appropriate.

One additional factor in regard to seeding rates and maximizing yield is planting date. Research has indicated that later planting dates may require higher populations in order to maximize yields. From a practical standpoint, producers planting cotton in June, where they intend to maximize yields (irrigation, etc.), should plant higher seeding rates than those previously mentioned and should aim for a final stand of 2 plants per row foot.

PLANTING

"Knock-off" beds and plant in the center of a smooth uniform surface 12 to 16 inches wide. Wet beds may need to be leveled 1 to 4 hours ahead of planting. Equip planters with 6 to 8 inch wide depth bands or gauge wheels, or 12 to 16 inch wide gauge shoes to provide seed depth control and smooth drill area. Set planters to place seed 0.5 to 1 inch deep. Shallower planting may be more appropriate if soil crusting occurs or if other emergence complications are expected. The shallow depth range is also preferred for "dusting in" in dry soil and/or cool-weather planting, a greater planting depth is preferred for warmer weather planting if moisture is sufficient at planting and for several days thereafter. Cotton is very sensitive to deep planting, especially in crusting soils or when soil moisture depletes rapidly. Open center press wheels and low press wheel loading are preferred to minimize soil crusting. Planter adjustments may need to be made on a field-by-field basis to ensure optimal soil-to-seed contact.

Performing pre-plant planter checks and ensuring proper planter setup can help minimize planting mistakes that can affect stand establishment. Seed meters should be checked regularly before and during the planting season. Any worn or damaged part in the meter should be replaced as it can affect seed singulation (plant population) by causing skips or multiples. Check seed tubes before planting to make sure they are clean and free of any obstructions. Opening-discs need to be checked for correct blade diameter and sharpness. Replace disc-openers that are worn by more than 0.5

inches as they can result in shallower planting depths. Seed depth variations are common between the planter row-units so make sure to dig the seeds behind every planter row and check the planted seed depth. Soil type and field condition can also influence seed depth, therefore any changes in soil type or field condition would require additional depth checks to ensure correct planting depth. Recent planter studies have demonstrated that planter downforce needs to be adjusted for prevalent soil texture and field conditions (conventional, strip-till or no-till) to attain a more uniform and consistent seed depth throughout the field. Planting in a heavy textured soil or fields conditions where excessive crop residue (especially planting in cover crops) is present would require an additional downforce to attained the desired seeding depth. Additional information on evaluating planter performance and what to look for can be found in this UGA Extension publication: https://secure.caes.uga.edu/extension/publications/files/pdf/C%201231_1.PDF.

When planting cotton in conservation systems, utilizing a single-disc coultter and a pair of row-cleaners in front of opening disks can help in cutting and removing any excessive soil or crop residue and provide a clean furrow to plant seeds. Coultter is normally adjusted so that it operates at a slightly shallower depth (about ¼") than the opening discs to prevent loosening soil around the furrow and creating any air pockets. Similarly, row-cleaners need to be adjusted so that they are barely touching the soil surface to remove the clods or residue and not digging into the soil.

If "rip-plant" equipment is used, off-set row drill 2 to 3 inches to one side of ripper shanks to reduce risk of stand loss from "fall-in." Contamination of the preplant incorporated herbicide treated zone with untreated soil resulting in grass emergence in the drill occasionally occurs behind ripper-planters. This can be minimized by using ripper shanks with a sharp rather than flat leading edge and by not planting in wet soil.

With good soil moisture and warm temperatures at planting, seedlings usually begin to emerge in 5 to 7 days with full stand in 8 to 11 days, but can be delayed or complicated by seedling diseases or rapid moisture depletion. Physical hazards to establishing stands that occasionally occur during this period include hard soil crusts and blowing sand. The adverse effects of both can be greatly reduced with rotary hoe or rolling cultivator operations. These implements should be operated just deep enough to break the crust. An irrigation of 0.3 to 0.5 inches can be used to soften or weaken a crust and accomplish the same objective. Timing this operation is critical. If a hard crust is evident when the seed root is 0.6 to 0.75 inches long, it should be broken immediately, being careful not to completely uproot more than 20 to 25 percent of the seedlings. Soil crust strength can be measured with a small pocket penetrometer. Emergence decreases rapidly at soil strengths above 10 psi especially when cotton is planted deeper than 1 inch.

CONSERVATION TILLAGE

Conservation tillage practices are employed on about 50 percent of the Georgia cotton acreage. In Georgia, conservation tillage and strip tillage are essentially synonymous. Incentives for such systems include reduced trips over the field, reduced labor and equipment costs, and soil and water conservation. After several years in reduced tillage, a slight buildup in overall organic matter often occurs, with significant increases in the upper half inch at the soil surface.

Success in conservation tillage requires a commitment to "make it work." Not surprisingly, there are pockets in the state of devotion to this methodology and adoption of the technology seems to

grow more rapidly in these areas. Farmers gain confidence from watching successes on neighboring farms, and thus, are willing to attempt a significant change in production practices. Successful conversion to conservation tillage is rarely piecemeal, it requires a total change in equipment and management. Required equipment includes a strip till unit, sprayer, and hooded sprayer or high residue cultivator.

Historically, the greatest challenges of reduced tillage systems have been stand establishment and weed control. Strip tillage implements have eased the complications of obtaining a stand by creating an environment similar to conventional seedbed preparation. For reduced tillage systems, burndown herbicides replace preplant tillage as the means of eliminating vegetation. The increased reliance on herbicides requires careful selection of products and rates as well as timely application.

Strip-Till Equipment

Strip till equipment includes tillage implements which provide a narrow zone of tillage in the crop drill. These implements remove weed or cover crop debris, subsoil under the row, and provide a reasonable seedbed for planting cotton. Several brands are available, and possible options include variations in coulters and rear closing/mixing tools.

General Problems

Conservation tillage systems are not without problems. Success demands careful planning and management. In most situations, growers should begin a year in advance in preparations for changes to conservation tillage. Planting into residues or untilled surfaces requires use of specialized equipment and increased reliance on agrichemicals. Inclusion of cover crops may increase management and expense. In addition, cover crops may drain needed moisture in a dry year or retain excess moisture in a wet spring. Reduction in tillage may cause changes in pest complexes, for example, proliferation of certain perennial weeds. Weed control is further complicated by the inherent inability to incorporate dinitroaniline herbicides, which provide the backbone of annual grass and small seeded broadleaf control in conventional systems.

Soils

The presence of covers often results in slightly cooler soil temperatures, which may delay planting and/or increase seedling disease. Reduced tillage generally improves soil moisture, although the presence of covers may deplete soil moisture in a dry spring or conversely, retain excessive surface moisture in a wet spring. Either situation may delay or hinder cotton stand establishment. Though few trials have documented advantages of particular cultivars in conservation tillage, potential stresses of cool temperatures suggest the need for planting cultivars with good early season vigor.

Long term reduced tillage may cause compaction in some soils, but in others, soil tilth may increase. Significant increases in organic matter require continuous conservation tillage for at least 3 to 5 years. Shallow fall disking or chisel plowing smooths field surfaces, providing a level seedbed for subsequent spring planting of cotton. Long term use of controlled traffic patterns may eliminate the need for subsoiling every year.

Cover Crops

Use of seeded covers increases cost and management but with benefits of added surface residues, soil and water conservation, wind protection, and possibly grazing, seed production, or N fixation. For compliance purposes, surface litter must provide 30 percent cover of the soil immediately after planting to qualify as "conservation tillage." Cover establishment can be accomplished by aerial

seeding, spreading with fertilizer, or standard drill seeding in the fall. Cover crop establishment methods which do not include fall tillage, favor establishment of wind-dispersed, cool season weeds such as horseweed. In crops such as soybeans or cotton, aerial seeding prior to leaf drop aids in cover crop establishment. Seeding rates can be lower than used for forage or grain production; however, many growers suggest that full seeding rates are needed to gain competitive advantage over weeds. In some situations, fallow or natural weed cover may be an economical alternative, provided they develop a sufficient winter cover.

Generally, small grain cover crops are easier to deal with than legumes. With high fertility, however, small grains may produce excessive growth, thus increasing problems with strip tillage and planting equipment and requiring slightly higher N rates (in cotton). In lower portions of the state, double crop wheat works in some years, although later planted cotton is at risk to early frost. Among the small grains, rye is probably the most adaptable. It is easiest to kill, easy to establish, and provides aggressive fall growth. In some instances, rye may provide too much vegetative growth and thus wheat may be a better choice. Ryegrass is extremely difficult to eliminate in the spring with burndown herbicides and should not be planted as a cover.

Though they may offset need for fertilizer N by about 30 lb/A, legumes pose several challenges. Legumes are often difficult to kill with burndown herbicides, and the release of ammonia during decomposition of green matter may injure cotton seedlings unless the cover is killed 2 weeks or more prior to planting. Legumes are also a host for cutworms and nematodes, the latter of which is a serious concern as increases in cotton acreage limit rotation. Most legume/conservation tillage systems have involved hairy vetch and crimson clover. In southern extremes and with early seeding varieties, crimson clover may work well in a reseeding program; in other words, clover may mature and produce seed prior to the time cotton should be planted.

Cover crops or weeds should be terminated with burndown herbicides 2 to 3 weeks before seeding cotton. Partial or strip killing of covers is usually not effective because of the competitive effects of the cover on the young cotton crop. Application accuracy of burn down sprays is facilitated by foam markers, light bars, or guidance systems. Termination of cover crops should be timed to limit excessive growth. This is of special concern with aggressive covers such as rye. Though research is not very precise on the matter, rye should be terminated before it reaches 3 to 4 ft tall, other small grains before they exceed 2 to 3 ft. The key is to desiccate the cover to prevent excesses in dry matter production and complications with strip tillage and soil/seed contact at planting.

Fertility

Because of limited opportunity to correct problems, a move into conservation tillage should begin only after establishing proper pH and fertility. Surface applications of lime and fertilizer are adequate for maintaining nutrient levels in reduced till systems. Starter fertilizers may have greater utility in conservation tillage because of cooler or compacted soils and the inability to thoroughly mix fertilizer amendments. Nitrogen fertility must be integrated with cover crop management--increase N rates for small grains, decrease for legumes--and petiole testing may be even more valuable in conservation tillage than in conventional tillage systems.

Strip Tillage/Planting

Achieving an adequate crop stand is foundational for successful cotton production. In conservation systems, strip tillage and planting equipment must effectively operate in surface litter and narrow, tilled zones to place cotton seed in firm contact with moist soil at a desired depth. Fortunately,

manufacturers and farmer-innovators have developed numerous implements for planting in reduced tillage situations.

Strip tillage and planting may be performed in the same or separate operations, with advantages for either approach. If both are performed in the same pass, there are fewer tracking problems and obvious savings in equipment and labor. Delaying planting 10 days or more after strip tillage reduces problems associated with litter decomposition and allows for moisture recharge of the tilled seedbed.

Rain or timely irrigation overcomes poor planting technique and poor soil/seed contact. Planting in a depression should be avoided because of potential problems with preemergence herbicide injury, postemergence weed control, and harvest. Standard strip tillage practices are not readily suited to establishment of raised beds and smooth row shoulders. However, a few growers have had success with fall bedding followed by cover seeding in order to create beds for the subsequent planting of cotton.

Insect Management

Insect management in conventional and reduced tillage systems is similar for most insect pests. However, differences do exist, most notably is the increased risk of cutworms in reduced tillage systems, especially if a legume cover crop is used. To reduce the risk of cutworm attack cover crops or winter weeds should be **controlled at least three weeks prior to planting**. No green vegetation should be present at planting, as it may serve as a reservoir host for various insects which may infest cotton. If the risk of cutworm infestation is high (i.e. green vegetation present, legumes cover crop, etc.), consider banding a cutworm insecticide such as a pyrethroid behind the planter as a preventive treatment. Increased infestations of false chinch bugs are sometimes observed in reduced tillage systems when a timely burndown herbicide was not applied. Grasshoppers are also more common in reduced tillage systems. We tend to observe fewer thrips in conservation tillage systems, but a thrips management program will still be needed. As fields remain in conservation tillage for several years, fire ants (beneficial) tend to increase.

Disease Management

Cooler temperatures and decaying vegetation contribute to increased potential for seedling disease in conservation tillage. Delaying planting or separating strip tillage and planting typically results in warmer, more favorable conditions and thus may aid in stand establishment in reduced till systems.

The interaction of covers with nematodes is not fully understood, but the preference of nematodes for certain legumes raises questions about their long term use in conservation tillage cotton. This is especially true for clovers and vetches.

PLANT AND FIBER DEVELOPMENT

Upland cotton (*Gossypium hirsutum*) is a perennial, tropical plant that has been bred and adapted for annual crop production in temperate climates. Cotton develops on a somewhat predictable schedule, although water and temperature stresses may have profound effects on growth rate.

Plant monitoring and mapping help determine if the plant is growing and fruiting normally. Assuming a lack of moisture stress or injury from one of many potential above or below ground

pests, plant growth is primarily influenced by temperature. Plant development proceeds approximately according to a heat unit model which uses 60° F as the base temperature. In this system, heat units are referred to as DD-60s and are calculated based on an average daily temperature °F minus 60° F. The formula is as follows:

$$\frac{\text{Max } ^\circ\text{F} + \text{Min } ^\circ\text{F}}{2} - 60 ^\circ\text{F} = \text{DD-60s}$$

For example, a day with a maximum of 86° F and a minimum temperature of 70° F produces 18 DD-60s, [(86 + 70 / 2) - 60 = (156/ 2) - 60 = 78 - 60 = 18 DD-60's]. Temperatures above 93° F should be entered in the formula at only 93° F since growth probably does not increase at higher temperatures. Current and historical heat unit accumulations for numerous locations across the state can be referenced at the website for the Georgia Automated Environmental Monitoring Network (www.georgiaweather.net) via the UGA cotton web page at www.ugacotton.com . For numerous locations across the state, this Network website allows calculation of current heat unit accumulation and comparison with data from recent years.

The following chart estimates growth rate based on accumulated DD-60s. Because growth and development are dependent on many factors in addition to temperature, these numbers are only approximations. A detailed discussion of cotton plant growth and development can be found here: <http://www.ugacotton.com/vault/file/UGA-Ext.-Pub.-Cotton-Growth-Development-2004.pdf>.

		<u>DD-60's</u>	<u>Days</u>
From Planting to:	Emergence	50	4 to 14
	Pinhead square	550	35 to 45
	First bloom	940	55 to 70
	Peak bloom	1700	85 to 95
	First open boll	2150	115 to 120
	Harvest	2500 to 2700	140 to 160

Plant Growth Monitoring

Monitoring cotton growth rate gives an index of vigor and should usually be initiated by the 8 to 10 leaf stage. Because of the variability of row profiles and cultivation practices, plant height should be measured from cotyledons to the terminal bud, not from the ground up. Cotyledons are the pair of seed leaves first observed after emergence. They are attached to the main-stem directly opposite from each other. By general agreement across the Cotton Belt, the node at the point the cotyledons are attached is counted as Node 0. As growth progresses, the cotyledon leaves fall off, leaving two small nodes near the base of the plant.

The first true leaf is Node 1 and should be visible in the terminal within 7 to 10 days after emergence. Subsequent main-stem leaves will emerge at approximately 3-day intervals (4 days under cool or stressed conditions). These leaves occur singly at each node and the stem area between each leaf or node is called the internode. Fruiting branches (FB) normally begin to develop at node 5 to 7 from one of the two tiny buds in the leaf axil or point at which the main-stem leaf is

attached. Fruiting branches develop a fruiting bud or square with a subtending leaf at 6-day intervals (possibly 7 to 9 day intervals under stress conditions) at one to three or more positions along the branch (referred to as FB1 for first position, FB2, etc.). The subtending leaf is a major source of photosynthate for the square, which flowers after about 21 days, and the boll, which develops and matures over a 6-week period after flowering. Vegetative branches (usually 2 or 3 per plant) develop at nodes or main-stem leaves below the first FB and sometimes from the second bud adjacent to a FB if the FB is injured. The goal for FB1 square retention at early bloom should be 80 percent. Experience in Georgia and in many other environments suggests that extremely high early retention rates may actually limit yields by limiting vegetative growth and total fruiting sites.

Cotton plants usually develop 21 to 23 nodes but an aggressive full-season varieties, may develop in excess of 25 nodes or main-stem leaves in long growing seasons with adequate moisture and/or moderate boll loads. Nodes beginning with numbers 5 to 7, and up to 20 to 22 potentially develop fruiting branches on which harvestable bolls develop. Cutout usually occurs when fewer than 5 nodes or main-stem leaves remain above the uppermost white flower (NAWF) at the first position (FB1). Boll retention in the top 2 to 3 nodes is usually very low since the plant is normally in cutout due to boll load, water, and/or nutrient stress.

Research indicates the crop can be defoliated when the uppermost, harvestable green boll is 4 nodes above the uppermost cracked boll (NACB = 4) without sacrificing yield and quality. When NACB is 5 or more, some yield or quality may be lost. Looking at this question from a different angle, a boll is sufficiently mature after accumulating about 750 DD-60s.

Plant Selection and Sampling for Monitoring Purposes

Usually, 20 normal plants should be counted / measured from each field beginning at the 8 to 10 leaf stage and on a weekly basis for maximum learning and database establishment. However, "short-cut" sampling where 8 to 10 plants or measurements are checked may be more practical for growers, county agents, and consultants.

Avoid plants with:

Damaged terminals

Spacings not like field average or plants next to skips or in clumps. Select the dominant plant in hill-dropped cotton

20 percent taller or shorter than field average.

Note: The following values are approximate and not well-defined by Georgia research
Plant Height (inches). Measure only from cotyledons to terminal bud.

Height/Node Ratio (HNR). Average plant height divided by total main-stem nodes = HNR or Vigor Index (inch/node).

Crop Stage	Vigor Index (Height/Node Ratio)		
	Normal	Stressed	Vegetative
Seedling Cotton =	0.5 to 0.75	-	-
Early Squaring =	0.75 to 1.2	0.7	>1.3
Large Square-1st bloom	1.2 to 1.7	<1.2	>1.9
Early bloom =	1.7 to 2.0	<1.6	>2.5
Early bloom + 2 weeks	2.0 to 2.2	<1.8	>2.5

Nodes Above White Flower (NAWF) at first position on fruiting branch (FB1):

Growth Stage	NAWF
Early Bloom	8 to 10
Peak Bloom	7 to 8
Cutout	<5

Ideal Plant (in very general terms)

Height = 44 to 50 inches

Total Nodes = 22 to 24

HNR = 1.8 to 1.9

First Fruiting Branch = node 6

Fruiting Branches = 12 to 14

Boll Retention = 67 percent or 8 to 10 FB1 bolls

Cutout = begins node 18 to 20

Managing the crop according to information obtained by plant monitoring is not yet possible due to lack of enough baseline data and environmental control under Georgia conditions. Generally, when monitoring indicates the plant is stressed or growing abnormally, the cause should be determined and corrected as soon as possible. Timely soil, petiole, and tissue analysis can detect nutrient deficiencies or excesses. Of course, water stress can only be relieved by timely rain or irrigation. Stress may also be caused by herbicide injury, disease, nematode injury, soil compaction, and temperature extremes.

Mepiquat containing plant growth regulators can be used to regulate excess vegetative growth. If excessive vegetative growth is due to fruit loss, the cause of fruit loss should be detected quickly, especially if related to insects. Other causes of fruit loss may include cloudy weather, heat/drought stress, heavy boll load, and cutout. Maximum yields can be obtained by optimizing growth conditions through proper management.

Fiber Quality and Development

A cotton fiber is a single cell that generates from the surface of the seed and elongates resembling a hollow tube. Fiber quality issues in Georgia gained significant attention concerning the 2003 crop, however great emphasis on fiber quality with respect to variety selection has drastically improved fiber quality of Georgia cotton. In any given year, due to environmental conditions, light spot grades, short staple, and high micronaire may be encountered, therefore it is important to understand fiber development and important quality parameters, and potential actions that could help avoid discounts.

Fiber length uniformity is a calculation determined by dividing the average fiber length by the average of the upper half fiber lengths (staple). This is difficult to comprehend, but in essence, the uniformity index reflects how many short fibers are present. Short fibers lower yarn strength,

reduce spinning efficiency, limit the use of lint for certain yarns, and increase imperfections in yarn. Uniformity can be influenced significantly by variety, boll feeding bugs, weathering of the open crop, and ginning. Relative comparisons of crop quality can be made by examining the Statewide Cotton Variety Testing data as well as other sources. The effect of boll feeding bugs on yield is well documented and we continue to learn about their effects on overall fiber quality. Weathering problems are aggravated by the limits of our harvest capacity, the interference of peanut harvest with cotton harvest (although the adoption of on-board module building pickers may help alleviate this issue), and our reluctance to push the crop toward rapid defoliation, boll opening, and harvest. Ginning can also have a profound effect on fiber uniformity. Excess heat (drying) and lint cleaning can result in breakage of fibers and reduce uniformity.

The two most important stages of development are fiber elongation and “thickening.” Elongation occurs primarily during the first 20 days after flowering, while thickening (internal deposition of cellulose within the fiber) occurs from about 15 to 20 days after flowering and continues for about 30 days (until 45 days after flowering). Inside the “tube,” rings or strands of cellulose are layered each day, intertwining and providing strength to the fiber.

The measure of elongation is staple, and the measure of internal fiber thickness is micronaire, often abbreviated as mike or sometimes mic. Variety, weather patterns, and boll feeding pest control play a role in determining fiber length and micronaire. Micronaire reflects the internal surface area or fill of the cotton fiber; that is, the thickness of the rings/layers formed within the cell. High or low micronaire generally corresponds to thicker or thinner deposits of cellulose, respectively. High micronaire (above 4.9) is usually associated with moisture or heat stress. Such conditions reduce boll set or boll size and concentrate carbohydrate production in fewer or smaller bolls, increasing cellulose deposition within individual fibers and increasing micronaire. Conversely, if stresses such as early frost or premature defoliation (from whiteflies, rain scald, etc.) curtail the development of bolls, low mic (below 3.5) may result.

Certain varieties have a tendency towards high mic, although the environment has the greatest influence on the final outcome and mic value. In fact, because high micronaire means a slightly thicker and probably heavier fiber, cotton breeders recognize that elevated micronaire is often a quick step to higher yield. High micronaire generally means coarse fibers which have reduced spinning efficiency, and has implications concerning dye uptake.

Fiber quality is influenced by numerous factors, including weather, management, variety, and ginning. Both length and micronaire are influenced by environmental conditions. WHEN stress occurs determines the characteristic most affected.

INSECT MANAGEMENT

Cotton insect management has changed dramatically since the successful elimination of the boll weevil as an economic pest and the commercialization of Bt transgenic cotton. Prior to elimination of the boll weevil, Georgia producers annually applied 10 to 20 insecticide treatments each season for control of boll weevils and other pests. Upon elimination of the boll weevil as an economic pest, the number of insecticide applications was reduced to four or five during 1992 to 1995. Utilization of Bt cotton, commercialized in 1996, has further reduced the need for insecticides by eliminating the need to treat tobacco budworm and significantly reducing the need to treat for corn earworm. Producers in Georgia have the opportunity to fully utilize an integrated approach to pest management (IPM) utilizing a variety of control tactics rather than relying solely on one method of control such as insecticide use. Scouting and the use of thresholds, cultural practices, variety selection, biological control, and insecticides used on an as-needed basis are the building blocks of an IPM program. Pests are managed so that economic damage and harmful environmental side effects are minimized while maximizing profits. In most IPM programs insecticide use decreases resulting in lower production costs, delayed resistance problems, and improved competitiveness and profitability. A successful and economical cotton pest management program mandates the use of this multi-tactical or IPM approach to insect control.

Figure 11. Mean insecticide applications applied on Georgia cotton, 1986-2021. The Boll weevil Eradication Program was initiated during the fall of 1986, insecticide applications applied by BWEP personnel are not included in the mean insecticide applications.

Scouting

Insect scouting is a **necessity**. All fields, both Bt and non-Bt cotton, should be scouted on a regular basis. Insect populations vary from year to year and even from field to field during the year. Fields should be scouted at least every five days, some scouts monitor fields twice per week. Although not recommended, once a week scouting may be acceptable on Bt cotton but there is associated risk with this reduction in field visits. **Once a week scouting on non-Bt cotton is unacceptable.** Management decisions should be made independently for each field based on the pest(s) situation.

Accurate monitoring of fields will allow growers to make timely applications of the correct insecticide(s) and rates to prevent damage from reaching economic levels. (See *Cotton Scout Handbook* for a detailed discussion of insects and scouting techniques and the Cotton Insect Control tables below for insecticides, rates, and thresholds.)

Beneficial Insects

Several species of predatory and parasitic insects are present in Georgia cotton. These natural controls are our most economical pest management tools and conservation of beneficial populations should be considered especially during early and mid-season. Big-eyed bugs, minute pirate bugs, fire ants, and *Cotesia* wasps are four important beneficial insects. The presence of these natural controls may delay the need to treat for some insect pests. The use of natural controls should be maximized in attempts to reduce production costs. See *Visual Reference Guide to Common Predators and Pests in Georgia Cotton* at the following link for more information: https://secure.caes.uga.edu/extension/publications/files/pdf/C%201161_7.PDF

Thresholds

Action or economic thresholds have been established for major cotton insect pests and are defined as the pest density at which action must be taken to prevent economic damage. The decision to apply an insecticide should be based on scouting and the use of thresholds. Thresholds for major cotton insects found in the Cotton Insect Control tables below should serve as a guide for decision making. **Scheduled or automatic applications of insecticides should be avoided.** An unnecessary application can be more costly than just the cost of the insecticide due to the destruction of beneficial insects. In the absence of beneficial insects, the risk of economic infestations for many insect pests increases. Application of insecticides on an as-needed basis allows beneficial insects to be preserved and reduces the likelihood of secondary pest outbreaks such as beet armyworm and spider mites

GA Cotton Insect Advisor App

The GA Cotton Insect Advisor is an application system for determining Extension prescribed insecticide treatments for management of cotton insect pests in the state of Georgia. The app will display the most appropriate insecticide or tank mix after the user provides the appropriate week of bloom, predominant stink bug species present, percent internal boll injury, and other pest species present. At present time, the app is intended for management of stink bugs only. Recommendations are based on information on the manufacturer's label and performance data from research and extension trials at the University of Georgia. GA Cotton Insect Advisor was developed by the University of Georgia Center for Invasive Species and Ecosystem Health in cooperation with the Department of Entomology with support from Cotton Incorporated.

The app utilizes the rules in Figure 12 for selecting stink bug insecticides with the objective of achieving acceptable stink bug control while minimizing the risk of flaring secondary insect pests which may be present but are at below established economic thresholds.

Expert System Rules

Decision Aid for Stink Bugs in Cotton

- **Week of Bloom:** treatment threshold triggers
 - Dynamic Threshold
 - Enter Percent Boll Injury
- **Stink Bug Species:** insecticide choice
 - Southern Green (<25% Brown): pyrethroid
 - Mixed (25-75% Brown): organophosphate
 - Brown (>75% Brown): organophosphate
- **Other Pest Species** (commonly found but below established action thresholds):
 - Weeks 2-5 of Bloom:
 - Caterpillars: include pyrethroid
 - Aphids: include dicrotophos, avoid acephate
 - SLWF: use bifenthrin, avoid dicrotophos
 - Mites: use bifenthrin, avoid acephate
 - Weeks 6-7 of Bloom:
 - Caterpillars: include pyrethroid
 - Aphids: include dicrotophos, avoid acephate
 - SLWF: use bifenthrin
 - Mites: use bifenthrin

Figure 12. GA Cotton Insect Advisor App decision rules for insecticide selection.

Resistance Management

In a population of insects, insecticide resistance levels to a particular class of insecticide increase each time that class of insecticide is used. Once an insecticide is used, its level of effectiveness will likely be reduced against subsequent generations within the season. Therefore **alternating the use of insecticide classes on different generations** of insects during the season is a recommended resistance management tactic. Since most cotton insect pests are highly mobile, such a strategy will be most effective if adopted by all producers in a large geographic area.

Thrips Management

Thrips are consistent and predictable pests of seedling cotton that infest cotton at emergence. Thrips initially feed on the lower surface of cotyledons and then in the terminal bud of developing seedlings. Excessive feeding results in crinkled malformed true leaves, stunted plants, delayed maturity, reduced yield potential, and in severe cases reduced stands.

At-plant systemic insecticides provide consistent yield responses and are used by most growers for early season thrips control. In-furrow applications or seed applied systemic insecticides are taken up by the plant as it germinates and develops providing protection during early growth stages. Commonly used at plant thrips insecticides include the neonicotinoid seed treatments

imidacloprid (Gaucho, and Aeris Seed Applied System) and thiamethoxam (Cruiser and Avicta Complete Cotton). In furrow liquid applications of imidacloprid or acephate and in furrow applications of aldicarb granules at planting are also options and provide increased control of thrips compared with seed treatments.

Supplemental foliar sprays may be needed if environmental conditions are not conducive for uptake of at-planting systemic insecticides or if heavy thrips infestations occur. Systemic foliar insecticides should be applied to cotton which had an at-plant systemic insecticide when 2-3 thrips per plant are counted and immatures are present. The presence of numerous immatures suggests that the at-plant systemic insecticide is no longer active. If no at-plant thrips insecticide is used, multiple well timed foliar applications will be needed.

The following factors related to thrips biology and ecology should be considered when planning thrips management programs:

Thrips infestations are generally higher on April and early May planted cotton compared with later planting dates.

Thrips infestations are lower in reduced tillage systems compared with conventionally tilled systems (winter cover crops should be killed at least 3 weeks prior to planting and no green vegetation should be present at planting).

Seedling injury and potential yield impacts from thrips feeding are compounded by slow seedling growth due to cool temperatures or other plant stresses (i.e. PRE herbicide injury).

A rapidly growing seedling can better tolerate thrips feeding.

Seedlings become more tolerant of thrips feeding as they develop; small seedlings (<2-leaf) are more sensitive to thrips injury in terms of yield loss compared with 3-4 leaf seedlings.

Slow growing seedlings will remain in the thrips “susceptible window” for a more extended time compared with a rapidly growing seedling; it is unlikely that seedlings which have reached the 4-leaf stage and are growing rapidly will benefit from supplemental foliar sprays.

Neonicotinoid seed treatments including imidacloprid or thiamethoxam have historically provided similar levels of thrips control and are active on thrips for 14-21 days after planting. However, imidacloprid seed treatments have provided more consistent control of thrips compared with thiamethoxam seed treatments in recent years. Thrips populations have shown reduced susceptibility to neonicotinoid (thiamethoxam and imidacloprid) seed treatments in Georgia, the southeast, and Mid-South. Thrips feeding and damage on seedlings treated with thiamethoxam appears to be more severe than on seedlings treated with imidacloprid. Although we are seeing reduced susceptibility, the neonicotinoid seed treatments remain beneficial and provide much needed protection during early growth stages when seedlings are most sensitive to yield loss from thrips. Both imidacloprid and acephate applied as an in-furrow liquid have provided improved control of thrips and longer residual when compared with seed treatments.

Acephate is an organophosphate and is an alternative at plant thrips treatment to the neonicotinoids. Acephate can be applied as a seed treatment (has limited residual, about 7 days) or an in-furrow spray where control and residual is improved compared with acephate applied as a seed treatment. One negative when comparing Orthene to neonicotinoids is the lack of cotton aphid control when acephate is used. We rarely observe cotton aphids on seedling cotton due in

part to the fact that neonicotinoids and aldicarb, which was the standard insecticide used for thrips control for many years, have activity on aphids.

Research and observation have shown that a supplemental foliar spray is often needed in addition to a neonicotinoid seed treatment when thrips infestations are high. We typically expect to see higher thrips infestations on early planted cotton in conventional tillage systems. Unless thorough scouting reveals thrips populations are below established thresholds, **a foliar thrips systemic insecticide should be considered at the 1-leaf stage in conventional tilled fields planted prior to May 10 when a neonicotinoid seed treatment is used.** In most situations this program will provide good thrips control, but the fields should be scouted regularly for thrips and injury following the foliar spray. In fields planted after May 10 or where reduced tillage is used, the risk of high thrips infestations is lower and an automatic foliar spray should not be applied; scout and treat when thresholds are exceeded. A more precise assessment of anticipated thrips infestations and plant injury can be obtained when using the Thrips Infestation Predictor for Cotton tool found online at <https://products.climate.ncsu.edu/ag/cottontip/>.

The Thrips Infestation Predictor for Cotton (TIPs) Tool uses planting date, temperature, precipitation, and knowledge of when and how intense thrips infestations will be to predict risk of thrips injury to cotton for specific geographic locations. Plant injury from thrips is a function of thrips pressure and seedling growth. The TIPs tool can be used to identify planting dates which are at greatest risk for thrips injury. High risk planting dates will require more aggressive thrips management compared with low risk planting dates to achieve acceptable thrips control. Management options for high risk planting dates would include the use of in-furrow liquid insecticides such as acephate or imidacloprid, in-furrow applications of aldicarb, or the use of a neonicotinoid seed treatment plus a supplemental foliar application at the 1-leaf stage. In low thrips risk environments neonicotinoid seed treatments will generally provide acceptable control. The TIPs tool should allow proactive decisions to be made relative to thrips management.

The TIPs tool will give the best predictions within 10-14 days after you use it, so use at multiple times during the planting and thrips management season would be beneficial. A description of the TIPs tool and how to run the tool can be found on the TIPs website. Dr. George Kennedy, NCSU entomologist, has prepared the webinar “Thrips Infestation Predictor for Cotton: An Online Tool for Informed Thrips Management”. The webinar includes an overview and how to use the TIPs tool and can be found at:

<http://www.plantmanagementnetwork.org/edcenter/seminars/cotton/ThripsInfestationPredictor>

The TIPs tool is a predictive model based on many years of data from across the southeast and has been validated several years since. However, there will be uncertainty with any forecast model. But we are confident that the TIPs tool, when used as instructed, will accurately forecast thrips risk for cotton. The TIPs tool will not replace scouting and sampling for thrips and thrips injury in cotton, but it does provide information which will improve our thrips management programs.

Aphid Management

Cotton aphid is a consistent and predictable pest of cotton in Georgia. Aphids will typically build to moderate to high numbers and eventually crash due to a naturally occurring fungus, *Neozygites fresenii*. This fungal epizootic typically occurs in late June or early July depending on location.

Once the aphid fungus is detected in a field (gray fuzzy aphid cadavers) we would expect the aphid population to crash within a week.

Aphids feed on plant juices and secrete large amounts of “honeydew”, a sugary liquid. The loss of moisture and nutrients by the plants has an adverse effect on growth and development. This stress factor can be reduced with the use of an aphid insecticide. However, research conducted in Georgia fails to consistently demonstrate a positive yield response to controlling aphids. Invariably, some fields probably would benefit from controlling aphids during some years. Prior to treatment, be sure there is no indication of the naturally occurring fungus in the field or immediate vicinity. Also consider the levels of stress plants are under, vigorous and healthy plants are able to tolerate more aphid damage than stressed plants.

Cotton leafroll dwarf virus (CLRDV) was detected in Georgia cotton during 2018. This virus is transmitted by cotton aphids. During 2019, field trials were established to examine the impact of aphid control on CLRDV. Weekly applications of recommended insecticides did not eliminate aphids from cotton. Additionally weekly aphid insecticides did not significantly reduce incidence of CLRDV plants compared with untreated cotton. Research efforts are ongoing to better understand this virus and potential impacts.

Tarnished Plant Bug Management

Tarnished plant bug is an occasional pest of cotton in Georgia and the lower Southeast. Primary damage caused by plant bugs is feeding on small (pinhead) squares in plant terminals. However, plant bugs may also feed on large squares, small bolls, and terminals. Plant bugs insert their needle like piercing sucking mouthparts into fruiting forms and feed on the plant juices. After a pinhead square has been damaged, it turns yellow to brown or black and easily falls from the plant when disturbed. Healthy undamaged squares will be firmly attached to the plant. When the square is shed by the plant, an elliptical scar where the square was attached remains. No visible damage is apparent on the outer surface of squares damaged by plant bugs. Plant bug feeding in the terminal may alter the physiology and result in a malformed plant. Large squares which are damaged will often remain on the plant and appear healthy and normal, however when the square blooms the flower will have warty growths on the petals and darkened anthers. This type of flower damage is referred to as a “dirty bloom”. Plant bugs may also feed on small bolls. Excessive feeding may cause boll shed, but most often localized lint and seed damage is the result. Callous warty growths on the inner surface of the boll wall will often form near the feeding site (appears very similar to stink bug damage).

Plant bugs and damage should be monitored from the time plants begin squaring through mid-bloom. Square retention counts are most often used to detect problems with plant bugs. Inspect one pinhead square in the terminal of plants, note if it is good or bad/missing and report the percentage of healthy green squares retained by the plant. Pinhead squares should be present when cotton has 6-8 nodes. They will be found at the base of the leaf petioles where they are attached to the mainstem in the top of the plant. The small square sits atop a short stem which will ultimately elongate into a fruiting branch. Our goal for plant bug management programs is to maintain 80 percent first position retention when we enter first bloom. Sweep nets (15 inches in diameter) are a good tool to monitor adult plant bugs in squaring cotton. As cotton enters bloom, a drop cloth or beat sheet is a better tool for plant bug scouting as it is more efficient in detecting immature plant

bugs. Sweep nets and/or drop cloths should be used in addition to square retention counts to make the most informed decisions on plant bug management. Additionally whole plants should be examined periodically during the year to monitor overall fruit retention.

Plant bug insecticides should only be used when thresholds are exceeded. This is especially important during squaring and early bloom as this is a critical time that beneficial insects are establishing in the field. Disruption of natural controls with plant bug insecticide applications will increase the risk of problems with other pests such as corn earworm, mites, and whiteflies.

Tobacco Budworm / Corn Earworm Management

Tobacco budworm (TBW) and corn earworm (CEW) appear very similar in the egg and larval stages and cause similar damage. However, they are different insects and their susceptibility to specific insecticides and Bt cottons differ. Three generations of TBW infest cotton each year. The first generation usually occurs in early June, the second in early July, and the last during August. These time periods vary from year to year and locality within the state but generally occur on a four-week cycle. Two generations of CEW infest cotton. The first CEW infestation is typically observed during mid-July when corn begins to dry down and a second generation occurs approximately four weeks later. Late in the season overlapping generations of both species are often observed.

It is important that we accurately distinguish between these two species. The adult or moth stage of TBW and CEW can be easily distinguished (See *Cotton Scout Handbook* for a detailed discussion of insects and scouting techniques). Observation of "flushing" moths during scouting and other field activities provides an opportunity to recognize which is the predominant species. TBW and CEW larvae can be distinguished upon careful examination with a hand lens or use of a dissecting microscope (see ugacotton.com). Populations of TBW infesting Georgia cotton are resistant to the pyrethroid class of insecticides and therefore **non-pyrethroid insecticides should be used to control TBW**.

On non-Bt cotton insecticide applications should target larvae 1/4 inch in length or less (less than 3 days of age). Coverage and penetration of the canopy with insecticide sprays are important. These basic principles of insect control are especially important if high populations or difficult to control larvae are present.

Distinguishing TBW and CEW is also important in Bt cotton. CEW is less susceptible to Bt toxins compared with TBW. Supplemental insecticide treatments may be needed for CEW control on Bt cotton whereas Bt cottons provide excellent control of TBW.

Pyrethroid Resistant Tobacco Budworm

TBW populations in Georgia exhibit moderate to high levels of pyrethroid resistance. Erratic and often unacceptable control would be expected if pyrethroids were used for control of TBW. In areas where TBW commonly infests cotton, producers should utilize Bt cotton which has provided excellent control. On non-Bt cotton, pyrethroid insecticides should **not** be used for control of TBW. Non-pyrethroid insecticides should be used in a timely basis for control of TBW on non-Bt cotton.

Corn Earworm and Reduced Pyrethroid Susceptibility

Susceptibility of CEW to pyrethroid insecticides has declined and become more erratic in some areas of the US during recent years. We suspect changes are occurring in Georgia, but have not experienced field control problems in recent years which may be due to low CEW infestations in cotton; actually few pyrethroids have targeted CEW for control in any crop. Dr. Greg Payne, University of West Georgia, annually collects CEW and TBW and conducts in-depth assays on CEW susceptibility to pyrethroids, spinosad, and Bt. These assays take time and typically results are not known for several months. To compliment these efforts, we also monitor susceptibility of CEW to pyrethroids using an Adult Vial Test (AVT) which has a quick turnaround time. To conduct Adult Vial Tests, moths are collected from pheromone traps and placed in pyrethroid treated vials (cypermethrin 5 µg/vial) and mortality is evaluated 24 hours later. Figure 13 illustrates the seasonal mean survival of CEW in AVTs conducted from 2006-2020. We observed high survival during the last four years. Note that survival during 2007 was also high and in that year we did experience some issues with control of CEW with pyrethroids in the field. Survival we observed in recent years is similar to that observed in areas where field control problems are occurring. Increased survival suggests that populations will be more difficult to control with a field application of a pyrethroid insecticide.

Current recommendations for control of corn earworm include the use of high rates of pyrethroids. Efficacy of pyrethroid sprays should be evaluated three days after application. If poor control of corn earworm is observed and other factors of poor control (coverage, rate, and timing of application) can be ruled out, a non-pyrethroid insecticide should be used. We cannot predict if this problem will develop further or if, when, or where it may occur. Results of Adult Vial Tests will be reported on ugacotton.com as needed during the growing season as well as reports of field control problems and any changes to current recommendations.

Figure 13. Seasonal mean survival of CEW in Adult Vial Tests (cypermethrin 5 µg/vial).

Bt Cotton Management and Corn Earworm Susceptibility to Bt Cotton

Commercially available Bt cotton technologies include Bollgard 2, WideStrike, TwinLink, Bollgard 3, WideStrike 3, and TwinLink Plus. **Bt cottons are not immune from economic damage from caterpillar pests** and have no activity on "bug" pests such as plant bugs and stink bugs. Thus, scouting for insect pests in Bt cotton (both caterpillar and bug pests) continues to be important. Currently available Bt cottons provide excellent control of tobacco budworm and good control of most caterpillar pests. However, supplemental insecticides may be needed for pests such as corn earworm and fall and beet armyworms. Be sure to monitor these cottons for early signs of infestation as the presence of numerous moths, eggs, or small larvae should influence insecticide selection when applications are made for other pests such as stink bugs.

Bt cotton is not and has never been immune to CEW. Since commercialization of Bt cotton, a percentage of Bt cotton grown in Georgia has required supplemental treatment of CEW in most years. There is variability in performance of the various Bt cottons. In recent years, susceptibility of CEW to Bt cotton has significantly declined in the US. This is due to a significant decline in susceptibility, especially to the first Bt gene (Cry1Ac). Some CEW populations are also less susceptible to the second gene (Cry2A). The Cry1F has never been very active on CEW, thus the reduced performance rating for WideStrike. Only a small percentage of Bt cotton has required supplemental treatment for CEW in Georgia during recent years so we have not observed this decline in efficacy in the field; this is due to low corn earworm infestations in cotton. Laboratory bioassays monitoring susceptibility suggest we could have problems in 2-gene Bt cottons if infestations are high. Additionally, researchers have seen reduced efficacy in Bt corn in Georgia and other areas of the southeast. Bt cotton must be scouted on a regular basis and growers must be prepared to act accordingly if thresholds are exceeded. Three-gene Bt cottons such as Bollgard 3, WideStrike 3, and TwinLink Plus provide improved control of CEW compared with two-gene Bt cottons. Relative efficacy of commercially available Bt cottons can be found in Figure 14.

Bt Traits	TBW Tobacco Budworm	CEW Corn Earworm	SBL Soybean Looper	BAW Beet Armyworm	FAW Fall Armyworm
Bollgard 3 (Cry1Ac+Cry2Ab+Vip3A)	+++	+++	+++	+++	+++
TwinLink Plus (Cry1Ab+Cry2Ae+Vip3A)	+++	+++	+++	+++	+++
WideStrike 3 (Cry1Ac+Cry1F+Vip3A)	+++	+++	+++	+++	+++
Bollgard II (Cry1Ac+Cry2Ab)	+++	+++	+++	+++	+++
TwinLink (Cry1Ab+Cry2Ae)	+++	+++	+++	+++	+++
WideStrike (Cry1Ac+Cry1F)	+++	++	+++	++	+++

Figure 14. Insect pest response (control) to Bt technologies in cotton. o=none, +=fair, ++=good, and +++=very good activity. Bt cottons are not immune to caterpillar pests and require that proper IPM principles and practices are employed.

Bt Cotton Resistance Management

Since Bt crops provide continuous season long activity against target pests, there is a high potential for one or both of these pests to quickly develop resistance if an effective resistance management plan is not implemented. Bt cotton was first commercialized in 1996. Since that time additional Bt genes have been stacked (2-3 Bt genes) in Bt cottons for improved performance and resistance management benefits. In addition to cotton, a significant percentage of corn contains Bt genes. Resistance management is required when planting Bt cotton or Bt corn. These resistance management plans are designed to delay and hopefully prevent the development of resistance. Bt genes in cotton and corn are similar and it is imperative that resistance management plans are followed in both crops to preserve the Bt technology. Bt corn utilizes a structured refuge where a percentage of non-Bt corn must be planted. Resistance management in Bt cotton uses a natural refuge (weedy host plants and non-cotton agronomic crops). Producers should maintain full knowledge of the details and follow resistance management requirements of use agreements with suppliers of transgenic seed or technology.

Stink Bug Management

The pest status of stink bugs in Georgia cotton and other areas of the Southeast have been elevated in recent years due to the reduction of broad spectrum insecticide use. Eradication of the boll weevil, greater utilization of natural controls, commercialization of Bt transgenic cotton, and development of caterpillar specific insecticides have all contributed to the reduced use of broad-spectrum insecticides. Routine use of broad spectrum insecticides, such as pyrethroids to control other pests in years past suppressed stink bugs below economic levels. In the absence of coincidental control of stink bugs, populations can build to damaging levels.

The most important species of stink bugs that we observe in Georgia are the southern green and brown stink bugs. Southern green is generally the most common. Organophosphate insecticides such as Bidrin provide excellent control of southern green and brown stink bugs. Pyrethroids provide good control of southern green stink bugs and are useful when populations of both caterpillar pests and stink bugs infest the same field. Research indicates that the brown stink bug is less susceptible to pyrethroids compared with southern green stink bug (control of brown stink bugs with pyrethroids increases when high rates are used). If brown stink bugs are present at economic levels an organophosphate insecticide should be used. However, the key to successful management of stink bugs in cotton is to know when and if an insecticide application is needed.

Stink bugs have piercing sucking mouthparts and damage cotton by feeding on the seeds of developing bolls. Stink bugs feed by piercing the boll wall with their beak and injecting a digestive enzyme into the boll in or near the seed to soften or dissolve plant tissues so the bug can remove them. In addition to physical damage, this process allows for entry of rot organisms that contributes to degradation of bolls reducing yield and quality. Bolls damaged by stink bugs may show sunken, purple spots on the outside boll wall; however this is not a reliable indicator of stink bug damage. Internal symptoms of injury are a much better indicator of stink bug feeding and include stained

or yellowish lint and/or callous growths or warts on the inner surface of the boll wall where the stink bug penetrated the boll. The wart or callous growth on the inner surface of the boll wall will form within 48 hrs on developing bolls. As bolls mature and open, damage often appears as matted or tight locks with localized discoloration that will not fluff. Severely damaged bolls may not open at all.

Scouting for stink bugs should be a priority as plants begin to set bolls. In addition to being observant for nymphs and adult stink bugs, scouts should assess stink bug populations by quantifying the percentage of bolls with internal damage. Estimating boll injury has proven to be a reliable technique for timing insecticide applications when needed. Bolls are considered injured if stained lint is observed or a warty growth is present on the inner surface of the boll wall. Bolls approximately the diameter of a quarter should be examined. Bolls of this age are preferred feeding sites for stink bugs can be easily squashed between your thumb and forefinger. It is important that bolls of this size (soft) are selected. If bolls which are the diameter of a quarter are not present, i.e. the first or second week of bloom, sample the largest bolls present. Monitor boll retention during the first week of bloom; if small bolls are damaged by stink bugs they will often be aborted (small bolls which are damaged by stink bugs will often have “jelly-like” contents in some locules). In addition to stink bugs, other bug species such as tarnished plant bug and leaf-footed bugs may injure developing bolls.

The number of bolls per plant which are susceptible to stink bugs is not constant and varies during the year. The greatest number of susceptible bolls per plant generally occurs during weeks 3-5 of bloom. During early bloom there are relatively few bolls present. During late bloom, many bolls are present but only a limited number may be susceptible to stink bug damage (individual bolls are susceptible to stink bugs in terms of yield loss until approximately 25 days of age). A **dynamic threshold** which varies by the number of stink bug susceptible bolls present is recommended for determining when insecticide applications should be applied for boll feeding bugs.

Week of bloom	Stink Bug Threshold (% Damage)
1	Retention
2	20
3	10-15
4	10-15
5	10-15
6	20
7+	30+

The boll injury threshold for stink bugs should be adjusted up or down based on the number of susceptible bolls present. Use a 10-15% boll injury threshold during weeks 3-5 of bloom (numerous susceptible bolls present), 20% during weeks 2 and 6, and 30%(+) during weeks 7(+) of bloom (fewer susceptible bolls present). Environmental factors such as drought and/or other plant stresses may cause susceptible boll distribution to vary when normal crop growth and development is impacted; thresholds should be adjusted accordingly. Detection of 1 stink bug per 6 feet of row would also justify treatment.

Research suggests that in addition to yield loss, excessive stink bug damage can reduce fiber quality characteristics. Fiber characteristics associated with length, maturity, and color are reduced when excessive stink bug damage is present.

Stink bugs are a primary pest of Georgia cotton and require management. Not all fields will require treatment, but for profit maximization scouting and treating on an as-needed basis is required. Fields at highest risk for stink bug infestations are those that have not received a broad spectrum insecticide during the past two weeks. Stink bug infestations are often first observed near field edges (especially near a peanut planting). Some innovative growers have chosen to scout and treat cotton near field edges independent of the entire field.

Silverleaf Whitefly Management

Silverleaf whitefly (SLWF) infested the majority of cotton acreage in Georgia during 2017. Historically SLWF is a localized pest requiring management in a relatively small geographic area. High populations of SLWF were observed across the Coastal Plain during 2017 and significant acreage required treatment with insecticides.

SLWF adults resemble tiny small white moths. Eggs are laid on the underside of leaves near the terminal. The first instar nymph is called a crawler. This crawler stage is the only immature stage which is mobile and only moves a short distance on the bottom of the leaf in search of a suitable place to feed. The crawler attaches itself to the leaf and the remainder of the immature stages are spent at this spot. Immature SLWF are oval and flattened in appearance and translucent to yellowish in color. On cotton during the summer, SLWF complete a generation in about 2 weeks. Development time is slowed when temperatures are cooler.

SLWF adults and immatures feed with sucking mouthparts. Damage ranges from reduced plant growth and vigor, general leaf decline, honeydew deposits on leaves and open cotton (honeydew accumulation on lint will negatively impact fiber quality and may impact spinning efficiency at mills), and premature defoliation. Yield reductions can be significant. Yield losses in field trials conducted in Tifton during 2017 averaged 32 percent and ranged from 5 to 64 percent when comparing the mean yields of insecticide treatments for individual trials with the untreated.

SLWF is an area-wide cross commodity problem. In addition to being a serious pest of cotton, SLWF is also a major pest of vegetables especially during the fall. It is important that all of agriculture address and manage SLWF. When all parties use sound SLWF management programs all will benefit. Following the general guidelines below, especially on a community and state-wide basis, should result in better management of SLWF area-wide.

SLWF Management Guidelines

Destroy SLWF host crops immediately after harvest; this includes vegetable and melon crops in the spring and cotton (timely defoliation and harvest) and other crops in the fall.

Scout cotton on a regular basis for SLWF adults and immatures. Routine sampling is required to identify the rate of SLWF population increase.

The presence of SLWF should influence the decision to treat other insect pests and insecticide selection.

Conserve beneficial insects; do not apply insecticides for any pests unless thresholds are exceeded.

Minimize or avoid insecticides such as organophosphates which are prone to flare SLWF when present.

If thresholds for SLWF are exceeded timely intervention with appropriate SLWF insecticides is a must. The goal of SLWF management with insecticides is to initiate control measures just prior to the period of most rapid pest population development. It is critically important that initial insecticide applications are well timed. If you are late with the initial application control will be very difficult and expensive in the long run. It is nearly impossible to regain control once the population reaches outbreak proportions.

All efforts should be made to minimize the risk of SLWF outbreaks and reduce the need to treat SLWF with insecticide. It is important to understand risk factors associated with SLWF in cotton. Although some risk factors cannot be controlled by growers, there are a few which can be incorporated into a production system. Below are several factors which influence the risk of SLWF in cotton:

Factors Affecting SLWF Risk

Winter Weather: SLWF can reproduce on over 600 plant species. SLWF survive the winter months on both cultivated and wild host plants. Mild winters as we experienced during 2016/2017 favor survival of SLWF. Freezing temperatures which kill host plants infested with immature SLWF effectively kills individuals on those plants. Higher survival during winter months leads to higher populations in the spring and the opportunity for populations to rapidly build to damaging levels.

Variety Selection: hairy leaf cottons are more susceptible to SLWF compared with smooth leaf cottons. There appears to be a direct correlation of SLWF infestations based on the degree of hairiness. Risk of SLWF is greatest on hairy varieties > light hairy > semi-smooth > smooth varieties. Plant smooth leaf varieties to lower risk of SLWF, especially if other risk factors such as planting date or proximity to SLWF crops are high.

Planting Date: the risk of SLWF problems increases as planting dates are delayed. SLWF complete a generation in about 2 weeks during summer months and populations can increase rapidly. The impact of SLWF on yield is dependent on the growth stage of cotton when SLWF infest the crop. SLWF stress the crop and potential yield loss is greater when infestations appear during squaring or early bloom compared with late bloom. The duration of control required for SLWF is also dependent upon planting date. April and early May planted cotton is at lower risk for SLWF problems compared with late May and June planted cotton.

Location (proximity of SLWF infested crops): crops produced can be viewed as sources and sinks for SLWF populations. What are the likely sources of SLWF which will infest cotton? Spring vegetable and melon crops are a source of SLWF infesting cotton. In the fall cotton is a source of SLWF infesting fall vegetables. The nearness of cotton to a SLWF infested field increases the risk of SLWF. This is likely why we have historically observed in localized geographic areas.

Beneficial Insects: conserve beneficial insects, only use insecticides for other pests when thresholds are exceeded. The presence of a few SLWF in cotton should get your attention. In general if we observe SLWF in cotton before the end of July we have potential problems.

In-Season Weather: hot and dry conditions favor SLWF development, survival, and population buildup. Thunderstorms and extended rainfall events such as tropical systems negatively impact SLWF populations on an area-wide basis.

Use IPM: scout your cotton for all insect pest on a regular basis. Use thresholds and only apply insecticides when thresholds are exceeded. When thresholds are exceeded, especially for SLWF, intervene with the most appropriate insecticide in a very timely manner. Incorporate cultural

controls for other pests with the objective of minimizing total insecticide inputs and conserving beneficial insects.

Irrigation: dryland (drought stressed) cotton is at higher risk for SLWF compared with irrigated (no drought stress) cotton. We have observed for several years that SLWF infestations are more severe in dry corners of pivot irrigated fields.

Scouting SLWF is a must. SLWF adults and immatures will be found on the underside of leaves. SLWF populations in cotton are best estimated by examining the 5th main stem leaf below the terminal. Main stem leaves are attached directly to the main stem by the leaf petiole. The top or first main stem leaf below the terminal is defined as the uppermost leaf which is 1 inch or greater in diameter. Adult and immature SLWF should be counted on the 5th main stem leaf below the terminal. However there are some exceptions, in rapidly growing cotton (pre-bloom) it may be necessary to examine the 6th or 7th leaf below the terminal. Our goal is to detect the presence of developing immatures. It takes time for eggs to hatch and the immatures to develop to a size which we can see. Use of a hand lens will aid in scouting. Conversely on cotton which has cut out and vegetative growth has slowed, leaves above the 5th leaf may be more appropriate sampling locations. Again our objective is to quantify developing immatures. Steps for efficient Sampling of whiteflies are below:

Scouting SLWF in Cotton

Familiarize yourself with the general location of the 5th main stem leaf below the terminal in each field scouted.

Select plants at random at least 25 steps into the field and at least 10 steps apart, being careful not to disturb plants you plan to sample.

Turn the 5th leaf over slowly by its tip or petiole and count the leaf as infested with adults if three or more adults are observed. Estimating adults will allow us to determine migration rates of SLWF infesting cotton.

Detach the 5th leaf from the main stem (if it fails to snap off easily you may be sampling a leaf that is too high on the plant).

Examine the bottom of the leaf for the presence of SLWF immatures. Count the leaf as infested if 5 or immatures are observed. A hand lens will aid in observing immatures.

Sample at least 30 plants per field.

Calculate the percentage of leaves infested with immatures. Treatment is recommended if 50 percent of the sampled leaves are infested with immatures.

Calculate the percentage of leaves infested with adults. This is beneficial when tracking buildup and migration of SLWF into fields.

Insecticides used for control of SLWF must be applied on a timely basis. Thresholds are designed so that timely application of insecticides can be applied just prior to the period of most rapid population development. Immature populations can go from threshold levels to very high populations in a week. Again be timely with insecticide applications when thresholds are exceeded. If you are late with the initial insecticide application control will be difficult and expensive in the long run.

The insect growth regulators (IGRs) Knack and Courier have long residual activity and minimal impact on beneficial insects. In general the IGRs are slow acting but perform very well when

applied on a timely basis. Conservation of beneficials is an important part of the IGR program. Knack is active on mature nymphs and eggs, SLWF adults exposed to Knack will lay sterile eggs. Courier is active on nymphs only. Neither IGR will directly control adults.

Assail, Sivanto, and Venom are active on all stages (immatures and adults). Control of adults is inconsistent due in part to re-infestation following application when populations are high. Our goal is to manage infield reproduction (i.e. control of immatures).

Invariably applications of insecticide for SLWF control will be late on some fields. In these situations application of an insecticide which is active on all stages is preferred as the initial treatment. Use of these insecticides which have activity on all life stages have quicker effects on SLWF populations compared with the IGRs. An IGR can be applied as a follow up spray to extend residual once the population is under control.

Below are two additional publications on SLWF management:

Cross-Commodity Management of Silverleaf Whitefly in Georgia found online at:

https://secure.caes.uga.edu/extension/publications/files/pdf/C%201141_1.PDF

Sampling and Managing Whiteflies in Georgia Cotton found online at:

https://secure.caes.uga.edu/extension/publications/files/pdf/C%201184_3.PDF

Terminating Insecticide Applications

The decision to terminate insect controls can be challenging in some fields but a few basic considerations will assist in that decision. When evaluating a field a grower must first identify the last boll population which will significantly contribute to yield (bolls which you plan to harvest). In some situations the last population of bolls which you will harvest is easy to see (i.e. cotton which is loaded and cutout). In others, such as late planted cotton, the last population of bolls you will harvest will be determined by weather factors (the last bloom you expect to open and harvest based on heat unit accumulation). Once the last boll population is determined the boll development or approximate boll age should be estimated. Depending on the insect pest, bolls are relatively safe from attack at varying stages of boll development.

The table below list approximate boll age in days which bolls should be protected for selected insect pests. Cooler temperatures will slow plant development and subsequent boll age values may increase in such environments. It is assumed that the field is relatively insect pest free when the decision to terminate insecticide applications for a pest is made.

Insect Pest(s)	Approx. Boll Age (days)
Corn Earworm	18-20
Tobacco Budworm	bolts fully sized
Stink Bugs	25
Fall Armyworm	bolts near maturity
Foliage Feeders soybean looper beet armyworm southern armyworm	bolts mature
Sucking Insects whiteflies aphids	harvest (honeydew accumulation on lint)

Boll Weevil Eradication Program (BWEP)

The BWEP is in the containment phase. Activities include reduced trapping but active spraying in areas where boll weevils are detected. Boll weevils are the responsibility of the program, so growers with suspected boll weevil problems should notify their local field supervisors. Everyone growing cotton is required to pay a per bale assessment for the BWEP. Boll weevil traps will be placed in fields by late July and monitored every three weeks for re-infestation. It is vitally important that traps are standing and functional. If a trap is accidentally knocked down or destroyed, stand it back up or contact your local field supervisor. All attempts to prevent re-infestations should be taken. A common means for boll weevils to reenter Georgia is on used farm machinery such as pickers and module trucks. If you plan to acquire machinery from a non-eradicated area, be sure it is boll weevil free. Contact the BWEP for more details.

COTTON INSECT CONTROL

Phillip M. Roberts, Extension Entomologist and Mike Toews, Research Entomologist

PEST	INSECTICIDE	MOA	FORMULATION PER ACRE	LBS. ACTIVE PER ACRE	REI/PHI (Hours or Days)	REMARKS
Aphid (Cotton)	<i>acetamiprid</i> Assail 30SG StraferMax70WP	4A	1.5–2.5 oz 0.6–1.3 oz	0.028–0.047	12 H/ 28D	Apply when aphids are abundant and seedling leaves are severely curled, or when "honeydew" is present in older cotton. A naturally occurring fungal disease often eliminates the need for sprays, but this epidemic occurs only after aphid populations reach high levels and tends to be less effective late in the season.
	<i>afidopyropen</i> Sefina 0.42	9D	3oz	0.0098	12 H/ 7D	
	<i>dicrotophos</i> Bidrin 8 Dicromax 8	1B	4–8oz 4–8oz	0.25–0.5	3D/ 30D	
	<i>flonicamid</i> Carbine 50WG	9C	1.4–2.8 oz	0.044–0.088	12 H/ 30D	
	<i>imidacloprid</i> AdmirePro 4.6	4A	0.9–1.7 oz	0.032–0.061	12 H/ 14D	
	<i>sulfoxaflor</i> Transform 50WG	4C	0.75–1.0 oz	0.023–0.031	24 H/ 14D	
	<i>thiamethoxam</i> Centric 40 WG	4A	1.25–2.0 oz	0.031–0.05	12 H/ 21D	
Beet Armyworm	<i>diflubenzuron</i> Dimilin 2L	15	4–8oz	0.0625–0.125	12 H/ 14D	Apply when 10% of squares or terminals are damaged, 10% of blooms are damaged and/or infested, or when 10 active "hits" are observed per 300 row feet. Beet armyworms may infest Palmer amaranth and move to cotton as larvae develop. Bt cottons will not control large beet armyworms moving from Palmer amaranth.
	<i>indoxacarb</i> Steward 1.25EC	22	9.2–11.3 oz	0.09–0.11	12 H/ 14D	
	<i>methoxyfenozide</i> Intrepid 2F	18	4–10oz	0.0625–0.156	4H/ 14D	
	<i>novaluron</i> Diamond 0.83EC	15	6–12oz	0.039–0.077	12 H/ 30D	
	<i>chlorantraniliprole</i> Vantacor 5SC	28	1.2–2.5 oz	0.047–0.098	4H/ 21D	
	<i>spinasad</i> Blackhawk	5	2.4–3.2 oz	0.054–0.072	4H/ 28D	
Bollworm/ Tobacco Budworm	NON-PYRETHROIDS					On non-Bt cotton apply when 8 small larvae are found per 100 terminals prior to first insecticide treatment, or when 5 larvae are found after first spray. Due to the threat of pyrethroid resistance, non-pyrethroid insecticides are recommended for control of tobacco budworm. Resistance management: Do not treat successive generations with insecticides that have the same mode of action. Bt cotton containing Bt genes are effective tools for use in bollworm and tobacco budworm management programs. Apply insecticide on Bt cotton when 8 larvae (1/4" or greater in length) are found per 100 plants.
	<i>indoxacarb</i> Steward 1.25EC	22	11.3 oz	0.11	12 H/ 14D

PREMIXED OR CO-PACKAGED INSECTICIDE PRODUCTS:

Products listed below are available as premixes or co-packages of 2 insecticidal active ingredients. When using premixed or co-packaged products, be sure the use of all active ingredients is necessary. Unnecessary applications or use of reduced rates of an active ingredient may lead to or intensify insecticide resistance. Labeled rates are listed with product names. However, see label for specific rates for target pests.

<i>bifenthrin, acetamiprid</i> (Argyle: 6–9 oz) <i>bifenthrin, avermectin B1</i> (Athena: 7–17 oz) <i>bifenthrin, imidacloprid</i> (Brigadier: 3.8–7.7 oz) <i>bifenthrin, chlorantraniliprole</i> (Elevest: 5.6–9.6 ozs) <i>dicotophos, bifenthrin</i> (Bidrin XP II: 8–12.8 oz) <i>fluopyram, imidacloprid</i> (Velum Total: 14–18 oz) <i>imidacloprid, cyfluthrin</i> (Leverage: 2.8–3.2 oz)	<i>lambda-cyhalothrin, chlorantraniliprole</i> (Besiege: 5–12.5 oz) <i>lambda-cyhalothrin, thiamethoxam</i> (Endigo: 4.5–6 oz) <i>methoxyfenozide, spinetoram</i> (Intrepid Edge: 4–8 oz) <i>novaluron, acetamiprid</i> (Cormoran 6–12 oz) <i>spinosad, gamma-cyhalothrin</i> (Consero: See label) <i>zeta-cypermethrin, bifenthrin</i> (Hero: 3.6–10.3 oz)

COTTON DISEASE AND NEMATODE MANAGEMENT: 2022 Updates

SECTION 1. UPDATE FOR THE 2022 GROWING SEASON:

Note: At the time submission of this chapter, information on disease and nematode resistance in cotton varieties new for 2022 is not fully available. Growers should continue to seek information for 2022 varieties from UGA Extension and from cottonseed dealers.

If you read no further, please consider the following:

1. Cotton growers will have one chance in 2022 to manage seedling diseases effectively. Once the furrow is closed, management options are cast. UGA Extension recommends carefully considering if additional seed treatments or in-furrow fungicides are needed based upon factors to include crop rotation, tillage, and environmental conditions, especially soil temperature and soil moisture.
2. Cotton growers will have one chance in 2022 to effectively manage nematodes. Once the furrow is closed, the opportunity to plant a nematode-resistant variety or to apply a nematicide, is over. Decisions for nematode management are best based upon field history of problems with nematodes and at-harvest soil samples for nematode assessment from 2021.
3. Cotton growers will have one chance to manage bacterial blight in 2022; the only tool to manage bacterial blight is to plant a bacterial blight-resistant variety.
4. Results from an increasing number of fungicide trials demonstrate the benefit of protecting cotton from areolate mildew and target spot with fungicides. Fungicides are likely to be in tighter supply for 2022, so growers should plan ahead.

The importance of diseases and nematodes in cotton production may be overlooked as the cotton plant is affected by fewer diseases than are other crops grown in Georgia and symptoms caused by nematodes can be easily attributed to other causes. Best management of diseases and nematodes in any crop should begin prior to onset of symptoms. Once symptoms appear, it is much more difficult, and sometimes impossible, to prevent yields losses from occurring.

Growers can effectively reduce the impact of diseases and nematodes on their cotton crop by making sound management decisions. These include:

- 1) use of crop rotation to minimize problems with nematodes and soilborne diseases
- 2) choice of planting date where temperature and soil moisture supports rapid germination and vigorous growth
- 3) fertility and plant growth management
- 4) choice of cotton variety, especially selection of disease and/or nematode resistant varieties
- 5) use of seed treatments and in-furrow fungicide applications for management of seedling diseases
- 6) use of appropriate nematicides
- 7) timely application of appropriate fungicides for management of target spot and areolate mildew
- 8) scouting of fields for early detection of disease and nematode problems
- 9) collection of soil samples for detection of plant-parasitic nematodes

Although difficult for some growers, good crop rotation with crops that are non-host for major

plant-parasitic nematodes (especially southern root-knot and reniform nematodes) and pathogens (for example *Rhizoctonia solani*) remains one of the most effective means of reducing losses in cotton. In the 2022 field season, growers will be able to select cotton varieties with resistance to southern root-knot nematodes, reniform nematodes, and bacterial blight; though a single variety may not be resistant to all of these pests. Growers will also have an expanding arsenal of fungicides to choose from for management of target spot.

From last season: The 2021 season will be remembered for the abundant rain and milder temperatures. Wet weather significantly increased severity of boll rot in many fields. Target spot and areolate mildew caused losses in some fields. Bacterial blight, though significant in a few fields, was of minimal importance statewide. Efforts to better understand the Cotton leafroll dwarf virus (CLR DV) continued in 2021. Anecdotal evidence suggests that the disease could have been present at trace amounts in nearly every field of cotton in Georgia; however, losses to this disease in 2021 were again minimal, at most, and largely restricted to several fields.

Listed in the initial section of this chapter are some of the most important disease and nematode considerations for producing cotton in the 2022 season. Each topic will be discussed in greater detail later in the chapter.

Areolate mildew (caused by the fungus *Ramularia areola*) is identified by the presence of a powdery growth of white-to-gray spores on the underside of the cotton leaves. Areolate mildew typically occurs later in the season and is favored by wet and humid conditions. Historically, losses to Areolate mildew were uncommon in Georgia; however, if the disease occurs early enough in the season, subsequent premature defoliation may impact yield. The fungus overwinters in infected crop debris from the previous season. Information is not available on varieties that may be more-resistant. Fungicides are effective in the management of areolate mildew and may increase yields by as much as 200 lb lint/A. However, fungicides are not always economically justified and they must be applied before the disease becomes severe and widespread in a field. Areolate mildew is most often observed in the southeastern production regions of Georgia, east of I-75. However, the disease has been much more widespread since 2017. Some growers applied fungicides (for example, Priaxor, Miravis Top, Quadris, Headline and generic azoxystrobin) to slow the spread of the disease. Research trials have confirmed that significant yield increases are associated with the judicious use of fungicides.

Cotton leafroll dwarf virus (CLR DV) will be of interest again in 2022, though this disease has had minimal impact on cotton production in Georgia. First reported in Alabama in 2017, then confirmed in Georgia in 2018, the full impact of this viral disease remains unclear. From the “First report of Cotton leafroll dwarf virus infecting Cotton in Georgia, USA” which was submitted for publication in the scientific literature, it is stated that, “During the 2018 growing season, cotton plants in several fields in Georgia were observed with foliar distortion, mosaic, cupping, curling, and downward rolling of leaves, dark greening, and shortened internodes, in the upper portion of the plants resembling that of Cotton blue disease caused by Cotton leafroll dwarf virus (CLR DV) (Family Luteoviridae, Genus Polerovirus). CLR DV is phloem-limited single-stranded (+) RNA genome virus transmitted by aphids in a persistent, circulative and non-propagative manner. Symptomatic leaves and petioles were collected from different fields at the University of Georgia-experimental farms in Tifton and other commercial cotton fields.” Presence of the virus has been

confirmed by Dr. Sudeep Bag at the University of Georgia. The virus is spread by cotton aphids; however efforts to manage the aphids have not affected the development of CLRDV.

Symptoms of CLRDV (as described “Report of A Research Review and Planning Meeting on Cotton Leafroll Dwarf Virus Orange Beach, Alabama – October 8, 2019” and drafted by R Kemerait, A. Hagan, T. Allen, and R. Nichols):

Cotton plants testing positive exhibit one or more of the symptoms described below. Symptom expression appears to differ by cultivar and by time of infection and subsequent disease progression.

1. In the early season, seedlings and young plants often show significant reddening, stunting, and downward cupping of the leaves. Additional symptoms include yellowing around the leaf margins and rugosity along the veins of the youngest leaves. In severe cases, death of the seedling/young plant may occur. With good growing conditions, some of these plants determined to contain the virus show signs of recovery following the initial symptoms; however, they will likely remain stunted and set few fruit.

2. Symptoms observed in mid-season progress to more reddening and cupping of the foliage, beginning first in the uppermost parts of the canopy. Stems and petioles may be red around their complete circumference and red veins may be observed in the leaves. New leaves are often crinkled or rugose in appearance. In extreme cases, large portions of the canopy are affected, and the foliage develops yellow, bronze, or red. Whereas extreme reddening has been observed in Georgia, such coloration has not been observed in Mississippi.

Additional symptom expression is likely to include significant compression of internodes near the terminal and little-to-no fruit production on certain symptomatic plants. Flowers on symptomatic plants may be devoid of pollen and have misshapen or elongated flower parts (e.g., elongated stigma with stamens wrapped around the stigma in a whorl pattern). With good growing conditions, symptomatic plants may recover their green color; however, they may remain stunted and suffer fruit loss.

3. Symptoms associated with CLRDV late in the season include a) compression of internodes, b) excessive elongation of vegetative growth in the upper main stem that produces a “whip” appearance, c) excessive, compact flowering, and in most cases flower/square abortion in the upper canopy, d) excessive vegetative branching from the bottom of the plant, e) stems that appear thicker than normal, f) misshaped (parrot-beaked) and abnormal boll size and shape, g) dark green coloration of the entire plant, sometimes with a bluish to purplish cast h) leaf tissue that feels thicker than normal (in some cases rubbery), i) reduced fruit set on severely infected plants, and j) excessive square production followed by rapid square abortion.

4. Symptoms associated with CLRDV on regrowth following defoliation include visible crinkling of the leaves, single-lobed or three-lobed leaves and, at times, reddening of petioles.

Diagnosing the presence of CLRDV-infected plants in the field can be difficult.

There are a number of reasons for this including:

1. Some symptoms associated with CLRDV can be the result of other causal factors. For example, several forms of stress and certain nutrient deficiencies can cause reddening of the foliage. Seedling diseases and Fusarium wilt can also produce symptoms similar to those of CLRDV early

in the season.

2. Symptoms associated with CLRDV can be variable and may be associated or exacerbated with the stress.
3. Symptoms of CLRDV can diminish over time. Plants appear to recover.
4. Symptoms associated with CLRDV appear to differ by cultivar. Some varieties present mild symptoms (e.g., leaf rolling, limited node stacking, no elongated terminal growth); Others present severe symptoms (e.g., leaf rolling, node stacking, enhanced terminal elongation, extreme vegetative branching from the bottom of the plant, a high rate of flower/square production followed by abortion).

Significant research and Extension efforts will continue at the University of Georgia and elsewhere in 2021 to better understand CLDRV, the spread of the disease, and management strategies for this newly recognized problem. **For 2021, our recommendations are to grow cotton as we have been successful in the past and to avoid late-plantings where possible. Early-season symptoms of CLRDV have been more pronounced in DG 3615 B3XF and DG 3799 B3XF than in other varieties; however, when the incidence of disease in a field is low, the impact on yield is likely small.**

Bacterial blight can cause significant yield loss and has been of concern to cotton growers since 2015. Because many of our newer cotton varieties have resistance to bacterial blight, the impact of this disease has decreased steadily in Georgia over the past few seasons. Bacterial blight has generally not been a problem since 2016, but without diligence from the cottonseed industry and from growers, it could become a problem again. The single most important and effective way to manage bacterial blight is to plant a more-resistant variety and to avoid planting susceptible varieties. However, growers must understand that despite susceptibility of some root-knot-nematode-resistant varieties to bacterial blight, the threat from root-knot nematodes is much higher in some fields than is risk to bacterial blight. Good news for growers now is that there are cotton varieties that are resistant to both the southern root-knot nematode AND to bacterial blight. Soon there will be varieties that are not only resistant to bacterial blight and southern root-knot nematodes, but to reniform nematode as well.

Varieties (2021) reported to have resistance to bacterial blight:

PHY 350 W3FE (also high resistance to southern root-knot nematodes)

PHY 360 W3FE (also with resistance to southern root-knot nematodes)

PHY 400 W3FE (also with resistance to southern root-knot nematodes)

PHY 430 W3FE

PHY 440 W3FE (also high resistance to southern root-knot nematodes)

PHY 443 W3FE (high resistance to southern root-knot nematodes and resistance to reniform nematodes)

PHY 480 W3FE (also high resistance to southern root-knot nematodes)

PHY 500 W3FE (also with resistance to southern root-knot nematodes)

PHY 530 W3FE (also high resistance to southern root-knot nematodes)

PHY 580 W3FE (also high resistance to southern root-knot nematodes)

NG 4689 B2XF

NG 5711 B3XF

When it comes to bacterial blight, please remember the following:

Losses to bacterial blight have occurred in some fields. However, in other fields where bacterial blight was found the damage was “cosmetic” with very little, if any, loss. The two most important tactics to manage bacterial blight are 1) plant resistant varieties and 2) manage crop debris from the previous cotton crop by burying it or through crop rotation.

Nematodes continue to be a significant problem for many cotton growers in Georgia,

Management of southern root-knot nematodes: For 2022, consider planting resistant varieties, to include DP 2141NR B3XF, PHY 350 W3FE, PHY 400 W3FE, PHY 440 W3FE, PHY 443 W3FE, PHY 480 W3FE, PHY 5003FE, PHY 530 W3FE, and PHY 580 W3FE.

Older varieties include PHY 487 WRF, DP 1558NR B2RF, DP 1747NR B2RF, ST 5600 B2XF, and ST 4946 GLB2 where southern root-knot nematodes are a problem.

Attention should be exercised again this year in variety selection based upon need for root-knot nematode resistance versus the importance of bacterial blight. For example, DP 1558NR B2RF, DP 1747NR B2RF and DP 2141NR B3XF have excellent resistance to southern root-knot nematodes, but are susceptible to bacterial blight.

Recommendations for varieties such as ST 5600 B2XF, DP 1558NR B2RF, DP 1747NR B2RF, and DP 2141NR B3XF would depend on three questions. 1) Is your field affected by southern root-knot nematodes? 2) Was bacterial blight a problem in your fields in 2015-2021? 3) What is your tolerance for risk to bacterial blight? If you have not had bacterial blight and are not worried about a little “cosmetic” injury, then root-knot nematode varieties should be considered. If you had significant impact from bacterial blight in 2015-2021, or you simply find any level of bacterial blight unacceptable, even if it does not affect yield and the variety performs well with nematode resistance, then you will want to select a variety with bacterial blight resistance and manage nematodes with nematicides or plant varieties that are resistant to both.

Management of nematodes with Telone II: Telone II is a very effective tool for management of plant-parasitic nematodes. Fumigation with Telone II (3 gal/A) using “risk management of zones” and “site specific” applications to maximize yields and minimize cost are important advances in management of nematodes affecting cotton. **NOTE:** The supply of Telone II is likely to be tight in 2022. Growers who would like to use Telone II in 2021 should contact their supplier early to make plans for obtaining needed product.

Management of nematodes: In 2022, cotton growers in Georgia can choose from several seed treatment nematicides to include Avicta Complete Cotton from Syngenta, BioST Nematicide 100 from Albaugh, and COPeO Prime from BASF. Growers also can select from Velum (fluopyram alone) and AgLogic15G (aldicarb) for management of all parasitic nematodes affecting cotton. Such treatments are expected to provide positive economic returns (increased yield versus cost of application) when nematode populations are at, or moderately above, economic threshold levels. Growers will have access to oxamyl formulated as Vydate-CLV from CORTEVA and ReTurn XL from AMVAC.

Fusarium wilt: This disease causes significant losses in some fields every year; management

options include crop rotation and management of nematodes. If southern root-knot nematodes are associated with the Fusarium wilt, then planting root-knot nematode resistant varieties could help manage Fusarium wilt. However, it seems that many fields affected by Fusarium wilt are often infested with the sting nematodes. If fields affected by Fusarium wilt are infested with sting nematode, then planting root-knot nematode resistant varieties will not help to reduce impact of the disease and nematicides are the only option. Fields affected by Fusarium wilt do respond well to fumigation with Telone II and sometimes to treatment with Velum or AgLogic.

SECTION 2. SEEDLING DISEASES OF COTTON

Seedling Diseases

Seedling diseases are widespread but typically not a major problem in Georgia cotton in most years. However, economic loss to seedling diseases can be significant at specific locations, especially when weather conditions are cool and wet at planting time and the grower is not able practice good crop rotation. Seedling diseases are caused by fungi that either survive on the seed or that live in the soil and infect seeds or developing seedlings. By far, the most common cause of seedling disease in Georgia is the fungus *Rhizoctonia solani*; however, *Pythium* spp. and *Fusarium* spp. May also damage young plants. Generally as the young plant matures it becomes less susceptible to infection by these pathogens.

Seedling diseases are differentiated by the stage of development of the seed and young plant when symptoms occur.

1. **Seed rot** is the first disease in this sequence and is easily identified by the presence of decayed seed; however the problem is often detected only after the grower notices “skips” in the stand. Seed rot may be caused a number of different fungi that can exist either in the soil or on the seed itself.
2. The second disease in this sequence is **pre-emergence damping-off** where a fungal pathogen attacks the young seedling after germination but before it cracks the soil surface. Like seed rot, pre-emergence damping-off results in skips in the stand.
3. **Post-emergence damping-off** occurs once the seedling has emerged from the soil. It is identified by the presence of a brown lesion at, or just below, the soil line that will eventually expand and girdle the young, succulent stem. Once the stem is completely girdled, the young plant will quickly wither and die. In the case of “hill-dropped” cotton, it is a common that if one seedling in a hill is diseased, all of the seedlings will be affected. Post-emergence damping-off is often referred to as “soreshin” in Georgia and is caused by the fungus *Rhizoctonia solani*. It is perhaps the most common seedling disease of cotton in the state and the one with which growers are most familiar. Although seedling disease caused by *Pythium* spp. is less common, it still occurs and is characterized primarily by a water-soaked root rot, either before or after emergence. As will be discussed later, it is important to identify the pathogen(s) that is/are responsible for seedling disease in a field as *Rhizoctonia solani* and *Pythium* spp. may not be controlled by a single fungicide.

Management of Seedling Diseases

Control of seedling diseases of cotton begins with the use of a fungicide seed treatment. All commercial seed sold in Georgia is pre-treated with at least two fungicides. **Growers should never plant cotton seed that has not been treated with a fungicide.** Seed companies continue to

incorporate more effective chemistries in their fungicide seed treatment package. Growers can reduce the effect of seedling diseases by avoiding conditions in which seeds/seedlings are at risk to damage from fungal pathogens. Cool, wet weather at planting and low soil temperatures produce an environment that not only slows germination and emergence, but may also favor fungal growth and infection. *Pythium* can be especially troublesome in saturated soils; *Rhizoctonia solani* is less dependent on soil moisture or temperature. **NOTE: Growers should avoid planting cotton seed when rain and colder soil temperatures are likely, even if seedling disease is not an issue.** Rapid germination and vigorous growth by the seedling are factors which help to insure the survival of the young plants. Slower growth early in the season gives the fungal pathogens more time to infect the vulnerable seed and seedling. The sooner the seedling develops hard, “woody” tissue, the less likely it is to be penetrated and rotted by fungi.

Good management practices to reduce the chance of disease include the following:

Plant in warm soils where the temperature at a 4-inch depth is above 65° F and where the 5-day forecast doesn't call for cooler or cooler/wetter weather. **NOTE:** Cotton growers should **NOT** plant cotton if at all possible when conditions are cool and wet or if the forecast calls for such conditions soon after planting, even if they plan to use additional fungicide treatments!

Plant seed on a raised bed since soil temperatures in the bed are generally slightly warmer than surrounding soil and drainage is likely to be better. Cotton planted in conservation tillage is not grown on raised beds, thus potentially increasing the threat from seedling disease.

Avoid planting seed too deeply. Seed that is planted too deeply results in longer periods before the young seedling cracks the soil surface, increasing the likelihood of seedling disease.

Correct soil pH with lime (pathogenic fungi are more tolerant to acidic soils than are cotton seedlings; pH should be in the range of 6.0 to 6.5).

Fertilize according to a soil test so as to promote rapid seedling growth; however care should be taken to avoid “burning” the seedling with excessive rates of at-plant fertilizers.

Avoid chemical injury through the use of excessive amounts or improper application of insecticides, fungicides, or pre-plant herbicides.

Plant only high quality seed as indicated by the percent germination in the standard seed and cool germination tests. Preferably, cool germination test results should be above 70%, though 60-69% is still adequate. **Additional premium seed treatment fungicides beyond the “base” treatment can significantly reduce the amount of seedling disease, increase stands, and potentially improve final yields where conditions are favorable for disease development.** However, significant outbreaks of seedling diseases are a sporadic problem. Because we cannot reliably predict which years will have greater amounts of seedling disease, growers can become justifiably frustrated when trying to determine the economic benefit of the additional fungicide.

As significant yield losses to seedling disease are sporadic in Georgia, UGA Extension does not recommend an additional fungicide treatment for each and every cotton field. Numerous field trials have been conducted by researchers at The University of Georgia assessing the benefits of seed treatments, hopper box treatments, and in-furrow fungicides. It has been very difficult to document significant yield benefits from these products despite increases in stand that may occur.

When a grower is assessing the need for additional protection from seedling diseases, he

should note the following.

Any field with a history of cotton seedling diseases should be considered a prime candidate for the use of these additional fungicides and seed treatments.

This is especially true when a poor history is combined with any combination of the following: a. cool, wet weather at planting, b. poor seed quality, c. conservation tillage (which tends to keep the soil cooler and perhaps moister than conventional tillage), d. a low seeding rate, or e. the use of an in-furrow insecticide or nematicide. The risk for losses to seedling disease increases in fields where multiple factors, as described above, apply.

Final note on seedling diseases: It is important to understand that fungicides which are effective on *Rhizoctonia solani* may not be effective on *Pythium* spp., and vice versa. For example, PCNB is active against *Rhizoctonia* but not *Pythium*. Metalaxyl, mefenoxam, and etridiazole are active on *Pythium* spp. but not *Rhizoctonia*. The tables below includes detailed information on chemical treatments for seedling diseases.

SECTION 3. FOLIAR DISEASES OF COTTON

Target Spot: Target spot is caused by the fungal pathogen *Corynespora cassiicola* and is most severe during periods of extended leaf wetness. Target spot is easily identified by the presence of marble-size spots on a leaf that frequently demonstrate a pattern of concentric rings. Infection and premature defoliation typically begin in the lower leaves of the plant and progress up the plant. Significant defoliation can occur very quickly after initial detection of the disease. Defoliated leaves often retain their green or green-yellow color. Lesions are also found on the boll bracts and possibly on the bolls themselves. Fungicides have been shown to aide in the management of this disease.

Special Notes for target spot: The most obvious symptoms associated with foliar diseases of cotton are spots and defoliation. The spots on the leaves likely decrease the ability of the leaf to produce the sugars that feed the growing plant and the developing bolls. Premature defoliation (loss of leaves) of the cotton plant may result in one of several scenarios.

First, if only older leaves lower in the canopy are lost, then the defoliation is unlikely to have a negative impact on yield. Older leaves generally are not productive and loss of a limited number of leaves may actually increase airflow and decrease humidity in the canopy.

Second, if premature defoliation extends upward in the canopy and results in loss of active, productive leaves, then yield may be affected. The subtending leaf associated with a boll is important for development of that boll. If such leaves are lost, then young bolls may be aborted or development negatively affected.

Third, if premature defoliation extends to the top of the plant, then the youngest bolls are unlikely to fully develop and open. For these and other reasons, it is important to promote healthy leaves and a healthy canopy of foliage.

IF YOU REMEMBER NOTHING ELSE ABOUT TARGET SPOT:

Target spot causes significant premature defoliation of the cotton crop.

Target spot is common in cotton in the southeastern United States.

Target spot will be most severe in fields with rank growth. The risk to target spot can be

reduced by careful management of the growth of the crop.

Fungicides (Headline, Priaxor, Quadris, Elatus, Miravis Top, and Twinline) can reduce premature defoliation resulting from target spot, but not Stemphylium leaf spot.

Based upon trial results, timings of applications that most consistently reduce premature defoliation are those that are made during the first and third weeks of bloom; the third week of bloom seems especially critical. (NOTE: growers can verify the best timing for application of fungicides by scouting fields before disease occurs.) Use of Priaxor at first bloom followed by Headline (or Quadris) at second application is an effective way to improve disease control and to minimize the risk of fungicide resistance. Priaxor is a pre-mix of Headline and Xemium.

No fungicide program yet assessed in Georgia has effectively eliminated premature defoliation when disease is severe.

In our studies, there has been tremendous variability in yield associated with use of fungicides to protect against target spot. It is not uncommon to find little or no yield increase associated with the use of fungicides; however in other cases (typically the most severe) numeric increases of as much as 200 lb/A lint are observed.

Fungicides are an important and valuable tool in the management of target spot; however they are not needed in every field where target spot is observed. Presented at the conclusion of this section is a draft of Risk Index for Target Spot to aide growers in determining where best to use a fungicide.

Where abundant rainfall (or irrigation) and warm temperatures occur during a season, a significant portion of the cotton crop across the Coastal Plain may be affected by target spot. In mild cases the diseased spots are a curiosity; in severe cases up to 80% defoliation may occur across large areas of a field. Target spot may affect all varieties of cotton grown in Georgia, though some may be affected more than others. Excessive cotton growth where periods of leaf wetness are extended is most often associated with outbreaks of target spot.

Rainfall and irrigation help to spread target spot in at least two ways.

First, rain-splash helps to move spores of the target spot pathogen from debris on the soil to lower leaves of the cotton plant, where infection occurs leading to production of leaf spots.

Second, rainfall and irrigation provide the moisture needed for spore germination and infection to occur. Moisture is also important for the production of spores on the spots and for their dispersal and infection of new tissue.

Rainfall and irrigation are critical for the production of cotton in Georgia; however anything that increases periods of leaf wetness, to include dew, will facilitate the development of target spot. Although management of leaf spot diseases will be discussed elsewhere, below are factors that UGA Cooperative Extension believes increases the risk of a cotton crop to target spot. As risk to target spot increases, the potential benefits to use of a fungicide to protect yield also increase.

Factors that are to likely increase risk to target spot of cotton. (See also draft “Risk Index for Target Spot” at conclusion of the Cotton Disease and Nematode Management section):

Cotton planted in short rotation, especially in fields where target spot has been a problem in the past.

Rank growth in the field, either because of management of other factor, e.g., variety.

Field receives overhead irrigation.

Abundant rainfall in a growing season coupled with warm temperatures.

Other factors that may contribute to increased risk to target spot include variety selection (research is being conducted now to assess such) and reduced tillage systems (that may allow spores of the fungal pathogen to survive in the crop debris).

Factors to consider for use of fungicides for the management of target spot:

The “final” fungicide program has not been established for the management of target spot; however an effective program will include 1-2 applications of Priaxor, Elatus, Miravis Top, Headline, Quadris or Twinline.

Timing of the first spray will vary based upon weather conditions during a season; however considerations for timing will include points below:

Increased risk to the disease (as assessed above).

Detection of small amounts of disease in the field, before the disease has become established and certainly before significant defoliation has occurred. (Note: Best management for any plant disease is achieved by protecting the crop BEFORE disease is established in the field. Because we still have much to learn about target spot and because there are many fields that may not respond to use of fungicides, growers may choose to wait to see if the disease can be found in their field. Such a “wait-and-see” strategy requires careful scouting to assure success.)

Initiation of the fungicide program before the canopy of cotton foliage closes in order to allow for appropriate coverage of the leaves. Current recommendation for initiating a fungicide application on cotton for target spot is when the crop is between 1 and 3 weeks after first bloom. Depending on conditions, e.g., wetter or drier, the optimal time for beginning a program could change.

Growers should begin to assess the need for a second application of fungicide no earlier than 2 weeks after the first application.

It is currently unclear if some varieties of cotton are more susceptible to target spot than are other varieties; however work continues to answer this important question. **Regardless of variety, the severity of target spot can be minimized by managing cotton growth with PGRs to eliminate rank growth.**

Managing Target Spot and Areolate Mildew

Target spot (*Corynespora cassiicola*) and areolate mildew (*Ramulariopsis gossypii*) are the two most important leaf diseases affecting cotton in Georgia later in the growing season. For both target spot and areolate mildew, judicious use of fungicides not only protects the crop, but can increase yield profitability as well. Another disease, Stemphylium leaf spot, is often even more common than either target spot or areolae mildew in Georgia's cotton crop. However, as Stemphylium leaf spot results from a deficiency of potassium within the plant, to date use fungicides has not proven to be an effective management strategy.

As of July 2021, target spot was widely found in cotton growing in southern Georgia. Abundant rain, high humidity, and rank growth of some cotton all contribute to the increased importance of target spot this season. Areolate mildew has not yet been confirmed in the state, but it is only a matter of time before it is found.

The two fungicides that have performed “best” against target spot have been Priaxor and Miravis Top, Close behind this pair has been Headline. Unfortunately, it seems that none of these fungicides may be readily available in 2022 to cotton growers in Georgia. This leaves azoxystrobin (sold under various trade names). Azoxystrobin is a fair-to-good fungicide for control of target spot; it is a good-to-very-good fungicide for control of areolate mildew.

Amistar Top, a combination of azoxystrobin and difenconazole, is another fungicide that could be considered when Priaxor, Miravis Top, and Headline are in short supply. The use rate for Amistar Top is 8-11.6 fl oz/A.

Growers should consider protecting their cotton crop from target spot between the 1st and 6th weeks of bloom IF the disease is present, or is likely to develop, and conditions are favorable for development and spread, and IF the crop has good yield potential. (As from earlier, conditions for development and spread of target spot are EXCELLENT in 2021.) Judicious use of fungicides can protect as much as 250 lb of lint where target spot is problematic. Where the crop is suffering from drought or poor growth from other causes, protection against target spot with a fungicide may not be warranted.

Stemphylium Leaf Spot: Stemphylium leaf spot is caused by the fungal pathogen *Stemphylium solani*; however the underlying cause of this disease is actually the result of a deficiency in potassium in the plant. This disease is analogous to Alternaria leaf spot (*Alternaria macrospora*) in Texas. Symptoms of this disease include a sudden reddening of the foliage of the cotton plant and the rapid appearance of numerous spots with ashy-gray centers and a dark purple margin. The centers of the spots frequently detach from the leaf giving the leaf a shot-hole appearance. The use of fungicides to manage Stemphylium and Alternaria leaf spot diseases has been largely unsuccessful.

Cercospora Leaf Spot: Like Stemphylium leaf spot and Alternaria leaf spot, Cercospora leaf spot (*Cercospora gossypina*) is often linked to a nutrient deficiency in the cotton crop and may form a disease complex with Alternaria macrospora and Stemphylium solani. Spots begin as small, reddish lesions that larger circular lesions with light brown centers; zonation similar to that of target spot may be observed. As this disease is associated with nutrient deficiencies, fungicides are not considered to be an effective control measure.

Areolate Mildew: Areolate mildew, caused by the fungal pathogen *Ramularia areola*, has been of limited importance in Georgia and is generally confined to the southeastern region of the state,

especially during periods of abundant rainfall. It has become more widespread since 2017 and use of fungicides to protect against this disease can be effective in protecting yield, if the disease occurs early enough in the season. The disease is easily identified by the presence of abundant white-to-gray sporulation on the underside of the affected leaves. The affected leaves often drop prematurely resulting in significant defoliation. This disease can be effectively managed with the use of fungicides, especially strobilurin fungicides; however it is not clear at this time how much yield loss is associated with the disease.

Ascochyta (wet weather) blight: *Ascochyta gossypii*, is a disease of sporadic importance in Georgia, especially during periods of cool weather with abundant rainfall early in the season. Hence, young plants are most often affected. The spots in the field can be tentatively diagnosed by the presence of tan lesions bordered by a dark ring; embedded in the lesion are dark fungal structures that appear like pepper grains. Though use of fungicides for effective management has been reported, such is generally considered unnecessary in Georgia. This disease tends to become of little significance as conditions become drier.

Angular (Bacterial) Leaf Spot: Angular leaf spot is caused by the bacterial pathogen *Xanthomonas citri* pv. *malvacearum* and is of increasing importance to cotton producers in Georgia. The disease is most common in periods of extend rainfall. Lesions/spots on the leaves are quite distinctive as they are defined by the veins on the leaf, thus creating the “angular” appearance. This pathogen can also cause water-soaked lesions on the bolls themselves leading to rot. As this is a bacterial pathogen, use of fungicides is not an effective management tool. This pathogen can be seed transmitted and also readily survives in infested crop debris.

Special Notes for 2022- Managing Bacterial Blight and Target Spot

Take-home points for bacterial blight/angular leaf spot

Bacterial blight is caused by the pathogen now known as *Xanthomonas citri* pv. *malvacearum*. Symptoms of bacterial blight start as tiny water-soaked spots and progress into characteristically angular shapes due to leaf veins limiting bacterial movement. Lesions appear on the upper side of the leaf (though the angular nature of the spots and “water-soaked” appearance is often more visible from the underside of the leaf), turn black as they expand and defoliation may occur. Systemic infections follow the main veins as black streaks; symptoms on the bolls are characteristically sunken water-soaked lesions. The lesions can be found at the base of the boll, shielded by the leafy calyx. The bacterial blight lesions are often further infected by opportunistic fungal pathogens which lead to further boll rot. The bacterial pathogen infects the plant tissues through natural openings and through wounds, such as those caused when plants are damaged by blowing sands in windstorm.

The pathogen (and subsequent disease) can occur in a field through planting of infested seed, survival from a previous cotton crop in crop residue, introduction through infested equipment and, perhaps, wind and blowing rain during storms. Though it is possible, spread of bacterial blight by insects, such as stinkbugs, is unlikely in Georgia.

Losses to bacterial blight are often small in a field; however losses can be 20% or more when a susceptible variety is planted.

From a study in conducted in 1964, cotton debris on the soil surface still contained the bacterial pathogen for 217 days (Perkins OK). However, cotton debris lost infectivity in 40 to 107 days in

moist soil. The pathogen was not present after tissue decomposed. No disease developed if infested residue was buried.

The most economical management of bacterial blight occurs when more-resistant varieties are planted. Incorporation of infected residue into the soil will help with decomposition of infected debris and reduce inoculum surviving between seasons.

Variety Selection for Management of Bacterial Blight:

Note: unless otherwise noted, ratings for bacterial blight have been provided by the seed companies. In 2017, UGA Extension cotton variety trials were more thoroughly rated for bacterial blight to corroborate industry ratings. See UGA Cotton Webpage for more information.

Varieties from PhytoGen Cottonseed:

PHY 312 WRF: rated “partially resistant”

PHY 333 WRF: considered susceptible

PHY 339 WRF: rated “resistant”

PHY 444 WRF: rated “partially resistant”

PHY 487 WRF: considered susceptible; however in UGA field observations, this variety appeared to be at less susceptible to bacterial blight than was DP 1558NR B2RF.

PHY 490 W3FE: rated as “resistant”

PHY 495 W3RF: considered susceptible

PHY 496 W3RF: considered susceptible

PHY 499 WRF: considered susceptible

PHY 575 WRF: rated as “resistant”

PHY W3FE varieties: rates as “resistant”

PHY 350 W3FE (also high resistance to southern root-knot nematodes)

PHY 400 W3FE (also high resistance to southern root-knot nematodes)

PHY 430 W3FE

PHY 440 W3FE (also high resistance to southern root-knot nematodes)

PHY 443 W3FE (also high resistance to southern root-knot nematodes)

PHY 500 W3FE (also high resistance to southern root-knot nematodes)

PHY 480 W3FE (also high resistance to southern root-knot nematodes)

PHY 530 W3FE (also high resistance to southern root-knot nematodes)

PHY 580 W3FE (also high resistance to southern root-knot nematodes)

Varieties from Delta and Pineland/Monsanto:

DP 1747NR B2RF rated as “susceptible”

DP 1646 B2XF: rated as “moderately resistant”

DP 1639 B2XF: rated as “partially resistant”

DP 1614 B2XF: rated as “susceptible”

DP 1612 B2XF: rated as “moderately susceptible”

DP 1558NR B2RF: rated as “susceptible”

DP 1555 B2RF: rated as “susceptible”

DP 1553 B2XF: rated as “susceptible”

DP 1538 B2XF: rated as “susceptible”

DP 1522 B2XF: rated as “susceptible”

DP 1518 B2XF: rated as “resistant”

DP 1820 B3XF: rated as “resistant”
DP 1840 B3XF: rated as “resistant”
DP 1851 B3XF: rates as “partially resistance”
DP 2141NR B3XF rates as “susceptible”

NOTE: For Delta and Pineland varieties, a “moderately resistant” variety will express fewer symptoms than varieties designated as “susceptible”. A “partially resistant” variety is heterogeneous for resistance to bacterial blight; a portion of the plants are resistant and the remaining plants are susceptible. “Moderately susceptible” varieties will express more symptoms than those that are “moderately resistant” and fewer than those that are “susceptible”.

Varieties from Stoneville/Bayer CropScience

Stoneville 5115 GLT: rated as “resistant”
Stoneville 5818 GLT: rated as “resistant”
Stoneville 5122 GLT: rated as “resistant”
Stoneville 5471 GLTP: rated as “resistant”

Varieties from Americot/NexGen

NG 5007 B2XF: rated “moderately resistant” (6/10 where 1 is poor and 6 is excellent)
NG 5711 BX3F (AMX 1711 B3XF) rated as highly resistant/immune
NG 4689 B2XF
NG 5711 B3XF

Below are questions commonly asked about leaf spots on cotton:

Question 1. What is causing the leaf spots in Georgia’s cotton fields?

Answer 1. There are three factors associated with outbreaks of leaf spots. First is the potassium nutrition in the cotton plant. Insufficient potassium leads to weakened cell walls in the leaves that are more easily breached by fungal pathogens. Insufficient potassium in the cotton crop may be the result of poor soil fertility, or leaching from the soil during periods of heavy rainfall, or during periods of drought when nutrients are not adequately moved into the plant. The second factor, extended periods of wet weather, created conditions favorable for development and spread of fungal diseases, abundant moisture aids in fungal growth and rain-splash and blowing rain aid in spread of disease. From 2015, a dryer-than-normal season may reduce severity of target spot. The third factor is the presence of inoculum (for example spores). Without sufficient inoculum, disease is much less likely to develop.

Leaf spots found in Georgia’s cotton fields include:

Stemphylium leaf spot (most common by far, is linked to nutrient deficiencies)

Alternaria leaf spot (fairly common, sister disease to Stemphylium leaf spot, is linked to nutrient deficiencies)

Cercospora leaf spot (fairly common, is linked to stress and nutrient deficiencies)

Target spot/Corynespora leaf spot (newly identified in Georgia, aggressive in 2009, 2010, 2012 and 2013, less important in 2011, 2014 and 2015 because of drought) is unrelated to nutrient deficiencies.

Ascochyta wet weather blight (not commonly observed but widespread early in 2013 because of abundant rainfall).

Angular leaf spot (bacterial blight), caused by a bacterial pathogen, was observed in some fields in 2011 in 2012 but was not of significant importance. **(Angular leaf spot was diagnosed only once in Georgia in 2014 but was more widespread in 2015 and again in 2016.)**

Areolate mildew was more widespread along the Coastal Plain of Georgia than at any other time in the past 20 years.

Question 2. Will disease (especially *Corynespora cassicola* (target spot) and *Stemphylium* sp.) that develops in one season predispose the same field to problems next season?

Answer 2. Although the spores of these fungal pathogens will likely survive until next season amongst the leaf litter and debris, I don't feel that this inoculum will greatly increase chances of severe outbreak of *Stemphylium* leaf spot from year to year. The deciding factor for this disease will be the weather that occurs in 2017. The drought during the 2014 season and the dry weather and high temperatures of 2015 decreased the risk to target spot but may have increased the risk to *Stemphylium* leaf spot. Outbreaks of *Stemphylium* leaf spot are historically more common in some fields than in others and in some regions of the state than in other regions. This is likely due to the relationship between potassium levels in the plant, soil type and weather patterns

The spores of *Corynespora cassicola* (target spot) that survive between seasons could lead to more severe infections in fields where a) the disease was a problem in the past, b) the field is planted using reduced/conservation tillage, c) cotton is planted behind cotton in rotation, and d) weather conditions include frequent rain events.

Bottom line: If our fields experience frequent rains and rank growth (target spot) or if potassium levels are low in the cotton plants (*Stemphylium* leaf spot), we will likely see another severe outbreak of one or both of these diseases.

Question 3. What is the impact of the spots that affect the leaves to the bracts and the bolls?

Answer 3. Three of the pathogens linked to leaf spots (e.g. *Stemphylium*, *Alternaria*, and *Cercospora*) are NOT boll rot pathogens and at best create superficial blemishes on the cotton bolls. However, under the right conditions (i.e. high rainfall or canopy moisture) it is possible that these superficial wounds could be colonized and exploited by more aggressive pathogens resulting in boll rot. The fourth pathogen, *Corynespora cassicola*, has been linked to boll rots elsewhere in the world. **The fifth, the bacterial pathogen *Xanthomonas citri* pv *malvacearum*, was found to cause boll rots in Turner and Ben Hill Counties in 2010 and in multiple counties in 2015 in 2016.**

Question 4. How can Headline, Priaxor, Twinline, Elatus, Miravis Top, or Quadris best be used to control foliar diseases we have now find in cotton fields? Is tebuconazole effective for management of target spot?

Answer 4. Fungicides like Headline, Quadris, Priaxor (a pre-mix of Headline and Xemium), Elatus (a pre-mix of azoxystrobin and solatenol), Miravis Top (a pre-mix of Miravis and difenoconazole)

and Twinline (a pre-mix of pyraclostrobin and metconazole) are fungicides that can be used to manage **target spot and areolate mildew**. Appropriate use of these fungicides can reduce the severity of leaf spots, reduce severity of premature defoliation, and protect yields. We continue to assess the use of each of these fungicides. Topguard (flutriafol) is labeled and we continue to assess its efficacy. Although tebuconazole can be legally applied to cotton, tebuconazole does not seem to be as effective against target spot as compared to the other labeled fungicides.

It is unclear whether a fungicide, no matter how good a fungicide, can have a significant impact on a disease whose cause is an underlying nutritional problem (Stemphylium, Cercospora, and Alternaria leaf spot diseases). Also, even if a fungicide is effective to one degree or another, it **MUST** be in place to protect the crop before the disease becomes widespread in a field.

Therefore, growers should consider the following:

If disease that is linked to a nutritional problem, such as Stemphylium leaf spot, or bacterial blight occurs in a field, a fungicide is unlikely to provide effective control.

In the case of target spot and areolate mildew, there is data to demonstrate that a fungicide treatment can reduce disease and defoliation and also increase yields. This is, obviously, most likely the case where the severity of target spot or areolate mildew is severe. Foliar diseases are likely to be most severe during periods of extended wet weather.

If a grower wants to test the efficacy of a fungicide, I **STRONGLY** advise leaving untreated areas in the field with which to compare disease control and yield to areas that have been treated.

If a grower wants to test efficacy, he should make a fungicide application **BEFORE** disease becomes established in the field and be prepared to follow with additional applications within 2-3 weeks after initial application.

Once disease becomes widespread in the field, it is unlikely that a fungicide would have any efficacy at all and the grower would be better served to save this money and use it elsewhere.

Question 5. What about applying a foliar fertilizer to improve nutrition in the leaves in order to control disease.

Answer 5. I will let our soil scientist address this; however I believe that **IF** a foliar application of fertilizer could **ELIMINATE** or greatly reduce the nutritional deficit before disease occurs, then it might be a viable management strategy. Otherwise, the foliar fertilizer would likely have no benefit in disease control.

SECTION 4. PLANT-PARASITIC NEMATODES AFFECTING COTTON

Nematodes

An estimated 60 to 70 percent of Georgia's cotton fields are infested with at least one species of potentially damaging nematodes. In a recent statewide survey of cotton fields (nearly 1800 samples were submitted by agents from randomly selected fields in 2002) approximately 69 percent of the fields were infested with root-knot nematodes, 2.8 percent with Columbia lance nematodes, 4.6 percent with reniform nematodes, and 0.6 percent with sting nematodes. While the southern root-knot nematode is responsible for the greatest amount of damage to cotton in the state, the Columbia lance and reniform nematodes also cause tremendous damage in more restricted areas, e.g. in the

heavier soils along the fall-line between the Piedmont and the Coastal Plain. Every cotton grower in the state of Georgia either has a problem with nematodes now or is at risk for such a problem should they lose the ability to practice effective crop rotation.

If damage to cotton from parasitic nematodes is such an important problem in Georgia, one may question why more attention is not devoted to this pest. There are three basic reasons. First, many growers do not recognize the symptoms of nematode damage as they can appear similar to drought stress, poor soil fertility, and injury from herbicides. Second, nematodes are microscopic worms that are not easily viewed by the growers. Third, many growers feel that they cannot afford to treat with nematicides because of the perceived cost associated with such treatments. Nothing could be further from the truth.

Symptoms of Nematode Damage Symptoms of damage from nematodes in a field are variable and are dependent on the species of parasitic nematode infecting the plants. Damage from reniform nematodes may be evident in the seedling stage where severely infected plants wilt and die. Stunting throughout the season is the most readily recognized symptom of severe infection by root-knot, reniform, and Columbia lance nematodes. In some cases, stunting may approach 50%, and infected plants are likely to show drought stress earlier than healthy plants. However, plants infected with low levels of reniform nematode may actually grow taller and larger than healthy plants as nutrition is going to vegetative growth rather than filling bolls. Although foliar symptoms are not the direct result of infection by parasitic nematodes, infected plants often show nutrient deficiencies, e.g. nitrogen and potassium, in the leaves. The leaves may be slightly yellowed, and in more advanced cases, interveinal chlorosis and leaf scorch may occur.

It is often useful to examine the root systems of plants suspected to be infected with parasitic nematodes to further diagnose the problem. It is important to carefully dig and remove the roots from the soil to preserve the finer secondary roots; roots infected with root knot nematodes often develop swellings and galls that are most evident on the finer secondary roots. The galls can be fairly small, but are visible if the roots are examined carefully. The tap roots from plants infected with the Columbia lance nematode are often severely stunted because of feeding at the growing tip by the nematodes. Secondary roots are also often severely stunted. Root systems from plants infected with reniform nematodes may appear normal because this parasite does not produce galls or severely stunted taproots. However, small clumps of dirt particles (containing egg masses) may be visible on the roots with the aid of a magnifying glass.

Crop Rotation

Crop rotation is a critical tool for nematode management in Georgia's cotton and should be used where economically feasible. Alternating cotton crops with non-host crops will help to reduce the size of the nematode populations in a field. Although this reduction may not be sufficient to eliminate the need of a nematicide in all fields, it will allow the grower to receive better effectiveness and larger yields from lower rates of nematicides. Common rotation crops to help manage nematodes damaging to cotton include the following: peanut and certain forage crops for southern root-knot nematode; peanut, and certain forage and vegetable crops for Columbia lance nematode; peanut, corn, and certain forage and vegetable crops for reniform nematode. Corn is a host crop for several important species of root-knot nematode, but recent research documents that the root-knot species found in soil samples from corn fields will almost always be the southern root-knot nematode regardless of previous crop. Therefore, when planting cotton following corn, it should be assumed that any root-knot nematodes found in a soil sample from corn will also be

damaging to the subsequent cotton crop. Additional information can be found in UGA Extension Bulletin 904 “Plant Susceptibility to Major Nematodes in Georgia.”

Growers who practice conservation tillage often have questions regarding cover crops and nematode management. Common cover crops such as wheat, oats and rye are somewhat susceptible to the southern root-knot nematode. However, because nematodes are inactive during the winter months when soil temperatures are cold and because wheat, oats and rye are fairly poor hosts for the southern root-knot nematode, these cover crops can be planted without increasing the nematode problem in the next cotton crop.

Leguminous cover crops, such as clovers and vetches, are also popular in conservation tillage, especially with the current cost of nitrogen. However, growers who have problems with southern root-knot nematodes in a field should exercise caution in planting vetches or clovers as cover crops because they are very good hosts. Though cold soil temperatures in the winter will reduce the build-up of nematodes on clover and vetch, the nematodes will become active once the soil begins to warm up in the spring. Growers who wish to plant vetches or clovers in a field where southern root-knot nematodes are present should seek to find a resistant variety, if one exists.

Nematodes and Stress

Nematodes are considered “stress” pathogens because of the sub-lethal damage that they typically cause to the root system. In addition to crop rotation, one very effective way to reduce the effects of nematodes in a field is to reduce the stress on the cotton crop. Fertility, pH, hardpan and water problems exacerbate plant injury due to nematodes and should be corrected. Irrigation can reduce, but not eliminate, yield losses caused by nematodes. Growers should wash soil from equipment that is being moved from infested to non-infested fields in an attempt to minimize the spread of the parasitic nematodes.

Nematicides

Nematicides are an important component in the management of nematodes on cotton. Despite their effectiveness, nematicides cannot completely compensate for poor crop rotation. Recommendations to use a nematicide are usually based on the results of a nematode assay from a soil sample collected near harvest of the previous year’s cotton crop. Nematicides, e.g. AVICTA Complete Cotton, COPeO Prime, NemaStrike, BIOst, Velum, AgLogic 15G and Telone II, can provide cost-effective control of nematodes when yield losses are expected to exceed approximately 10% or when results from a soil sample exceed a predetermined economic threshold. The choice of one of these products over another is influenced by factors such as the potential severity of losses to nematodes in a field versus the level of control offered by the product, application capabilities of the grower, and cost. Although growers may be concerned about the initial cost of using a nematicide in a field with damaging populations of parasitic nematodes, the resulting increase in yield will often provide a very good return on the investment. Nematode threshold levels and nematicide options also are given in Appendices III and IV. Additional information can be found in UGA Extension Bulletin 1149 “Cotton Nematode Management,” UGA Extension Circular 834 “Guide for Interpreting Nematode Assay Results,” and UGA Extension Bulletin 1160 “Controlling Nematodes with Soil Fumigants.”

Seed Treatments and Nematicides

AVICTA Complete Cotton is composed of Avicta (abamectin) for management of nematodes, Cruiser (thiomethoxam), for early season thrips management, and Dynasty CST for additional protection from seedling disease. Growers who wish to use AVICTA Complete Pack can either pre-order the product with their seed or have it treated at special facilities after acquiring the seed.

Other nematicide seed treatments for cotton today include:

COPeO Prime (fluopyram + imidicloprid)

BioST Nematicide 100: Active Ingredient: Heat-killed Burkholderia spp. strain A396 and spent fermentation media

From past research: After reviewing the data that has been collected for the nematicidal activity of AVICTA Complete Cotton and AERIS Seed-Applied System by the University of Georgia, it is evident that these seed treatments are a popular and valuable tool for growers. However, Temik 15G (5 lb/A) had efficacy at higher/more damaging populations of nematodes than do the seed treatment nematicides. This is based upon ratings of early season galling on the cotton roots and on final yields. Based upon the loss of Temik and the ease with which seed-treatment nematicides are used in the field, fewer growers no longer ask, “Is AVICTA Complete Cotton (or AERIS Seed-Applied System) AS GOOD as Temik 15G (5 lb/A)?” and should now ask “Is AVICTA Complete Cotton or AERIS or Acceleron N GOOD ENOUGH for my field and, if not, what other options do I have?”.

Use of Vydate C-LV (oxamyl) or ReTurn XL

Vydate C-LV is an insecticide/nematicide that is applied as a foliar spray to cotton typically at 17.0 fl oz/A between the 5th and 8th true-leaf stage of cotton development. This application is a supplemental treatment for earlier applications of Telone II or use of AVICTA Complete Pak or AERIS Seed-Applied System. Use of Vydate C-LV is quite popular with cotton growers in the mid-south (e.g. Mississippi), but much less so in Georgia. For whatever reason, it is difficult to show consistent yield increases when assessing Vydate C-LV in our trials; **however use of Vydate is certainly an option for growers who need additional protection from nematodes after cotton seedlings emerge. ReTurn XL (active ingredient oxamyl) is a similar product to Vydate C-LV and is from AMVAC**

Velum Total Technical Notes

Active Ingredients: Fluopyram + Imidacloprid

Chemical class: Pyrimidine + Neonicotinoid

Formulation: Soluble Concentrate - Contains 1.50 lbs. FLUOPYRAM and 2.17 lbs. IMIDACLOPRID per gallon

Rate: 14-18 fl oz/A

Mode of action: Nematodes & Diseases: Fluopyram [SDH-Succinate De-hydrogenase (SDHI) inhibitor (FRAC Group 7)] Nematode Spectrum: Nematodes - Root knot, Reniform, Lance

Insects: Imidacloprid [Nicotinic acetylcholine receptor (nAChR) agonist (IRAC Group 4A)

Xylem systemic

AgLogic 15G O&A from

Q. What is AgLogic Chemical, LLC?

AgLogic Chemical, LLC is an affiliate of MEY Corporation and holds the U.S. Environmental Protection Agency (EPA) registration for AgLogic™ 15GG brand aldicarb pesticide and returned this product to the market for the 2016 growing season. Bayer CropScience formerly marketed a similar product under the brand of Temik.

Q. What is AgLogic™ 15G aldicarb pesticide?

AgLogic™ 15GG is a carbamate pesticide that contains the active ingredient aldicarb that controls nematodes, a wide range of piercing and sucking pests and certain chewing pests through direct contact with treated soil and systemically from residues absorbed and translocated by the developing root system.

Q. What crops are currently labeled for AgLogic™ 15GG?

Currently labeled crops include cotton, peanuts, soybeans, sugarbeets, drybeans and sweet potatoes.

Q. What pests are listed for control on the AgLogic™ 15GG label?

Pests controlled include nematodes, thrips, aphids, leafhoppers, lygus, whiteflies and mites. Check the product label for the full list of pests controlled.

Q. Is AgLogic™ 15GG expected to perform comparably to its predecessor Temik?

Its performance is expected to be comparable to Temik 15G.

Q. Can I use the same application equipment for AgLogic™ 15GG that I used for Temik?

Yes. The same type of application equipment can be used for AgLogic™ 15GG that was used for Temik 15G. However, all equipment must be checked and recalibrated to ensure proper flow of the product.

Q. How will AgLogic™ 15GG be packaged?

Gypsum formulation is sold and distributed in 45 lb. boxes.

Q. Are there special requirements a grower has to meet to be able to buy AgLogic™ 15GG?

Yes. Growers must have a current Georgia restricted use pesticide license and pass an on-line certification course in order to purchase AgLogic™ 15GG.

Q. Why is a certification course required to buy and use AgLogic™ 15GG?

AgLogic Chemical, LLC is firmly committed to the conscientious labeled use and diligent stewardship of AgLogic™ 15GG brand aldicarb pesticide in order to ensure the continued long term availability of this valuable pest management product. The dealer and grower certification courses are the first steps in implementing the precautions and measures deemed important to ensure proper distribution, application, use, storage and if necessary disposal of the product.

Telone II and Development of Risk Management Zones as a tool for nematode management in cotton.

Plant parasitic nematodes, especially root-knot nematodes, are often unevenly distributed across a field. Because of this “patchy” distribution, the damage attributable to nematodes in a cotton field is often highly variable from one point to another. Much of this variation is the result of differences

in the characteristics of the soil.

Accurate identification of different risk zones in a field should be attractive to cotton producers. If growers can determine risk zones across a field based initially on soil type (measured indirectly through the use of soil electroconductivity values) and subsequent sampling for nematodes, then they can use this information to refine use of nematicides in a field. For example, in areas of the field where risk to nematodes is more severe, then growers may choose to use more effective, but more expensive, treatments such as fumigation with Telone II. Where risk to nematodes is known to be reduced, growers may choose to use nematicide seed treatments.

Growers who are interested in developing risk management zones for nematodes in their fields should consider the points listed below:

Southern root-knot nematodes are the key plant parasitic nematode affecting cotton in much of Georgia.

Southern root-knot nematodes are often unevenly distributed in a field; largely as a factor of soil type.

Populations of southern root-knot nematodes tend to be proportional to the percentage of sand in the soil in a field. Larger percentages of sand often support higher levels of nematodes; higher percentages of silt and clay (heavier soils) tend to have smaller populations of southern root-knot nematodes.

Southern root-knot nematodes tend to prefer the interstitial spaces of sands (spaces between sand particles) for ease of movement in the soil.

Risk management zones for management of southern root-knot nematodes are currently being studied and developed in a number of states, to include Georgia, South Carolina, and Louisiana.

In Georgia, Risk Management Zones are developed largely on the use of VERIS rigs that map soil conductivity in a field. Higher soil electrical conductivity (EC) indicates more silt and clay and less sand. Lower soil EC values indicates more sand.

Maps can then be drawn to split the field into zones with higher EC values and lower EC values.

The OPTIMIUM use of these maps is to focus nematode sampling efforts to confirm populations in higher risk zones and lower risk zones. It is NOT sufficient to simply determine choice of nematicide based upon soil EC maps.

Remember: Soil EC values indicate the possibility for different populations of nematodes but not necessarily the reality. For example, there are certainly very sandy fields in the state that have few if any southern root-knot nematodes, often because of great crop rotation. In other fields a grower may be able to define Risk Management Zones based upon soil EC; however the differences in EC may not be of biological significance and the entire field would benefit from a nematicide like Telone II (hence the need to take nematode samples.)

Finally, even though there may be Risk Management Zones in a field appropriate to treat with different rate/nematicides based upon nematode samples, there may also be OTHER agronomic factors (e.g. fertility, moisture retention, etc.) that may keep zones from yielding as hoped.

FINALLY: I truly believe that when used appropriately, risk management zones ARE a very important tool for the best cost-effective management of nematodes in Georgia.

Notes for 2022- Nematode management:

Question 1. If I have a nematode problem in my field, should I plant one of the nematode-resistant varieties?

Answer 1. As a grower you **MUST** consider this option (see further notes below). Before you make this decision, insure that the nematode problem in the field is caused by southern root-knot nematodes and not others, e.g. reniform, sting or Columbia lance.

Question 2. If I plant one of the root-knot nematode resistant varieties, do I still need to use a nematicide? Am I better off planting a “highest yielding variety” and treating with a nematicide?

Answer 2. The short answer is that these resistant varieties will certainly perform better than susceptible varieties in terms of decreased root-damage and reduced build-up of nematodes in the soil. This does not necessarily translate into increased yield. Recent data demonstrates that even the resistant varieties may benefit from use of a nematicide like Telone II when nematode populations are severe. However, growers who plant root-knot nematode resistant varieties are unlikely to see a benefit to treating the field with an additional nematicide (to include seed-treatment, Velum, AgLogic 15GG or Telone II.)

Question 3. What is the value in planting a root-knot nematode resistant variety?

Answer 3. As compared to a susceptible variety, root-knot nematode resistant varieties will have less root galling and root damage and much lower populations of nematodes in the field at the end of the season. Planting a root-knot nematode resistant variety is almost like planting a non-host; nematode populations are greatly reduced for the coming season. Resistant varieties with two resistant genes (e.g., DP 1558 B2RF and PHY 487 WRF) have greater resistance to root-knot nematode varieties than do varieties with a single resistance gene (e.g., ST 4946 BRF).

Planting root-knot resistant varieties will a) decrease root damage which leads to better growth of the plants and b) reduced nematode populations which benefits the next time cotton is planted in the field. Root-knot nematode varieties will not always out-yield susceptible varieties; however resistant varieties are less likely to need the protection from nematicides.

SECTION 5. FUSARIUM WILT

Fusarium wilt is a fungal disease that typically becomes evident in mid-season, though it can occur at any point in the growing season. **In 2013, 2014 and 2015, severe outbreaks of Fusarium wilt were observed in Pierce, Tift, Jeff Davis, Evans, Cook, Grady, Thomas and Berrien Counties.** Fusarium wilt is not currently a wide-spread problem in Georgia; however there are fields throughout the state where losses can be significant. For some reason, Fusarium wilt seems to be more problematic in southeastern Georgia than in other areas of the state. Fusarium wilt is becoming of increasing concern.

In cotton, Fusarium wilt is usually found in association with infections by the southern root-knot nematode, which has a synergistic effect on this disease. Although root-knot nematodes are most often associated with Fusarium wilt, other parasitic nematodes such as Columbia lance, reniform, and sting nematodes also injure cotton roots and increase the severity of the disease. As populations

of parasitic nematodes increase throughout the state from inadequate crop rotation, it is possible that Fusarium wilt will become a more serious problem. **Recommended control measures for this disease are to root-knot nematode-resistant cotton varieties and to control root-knot and other nematode infestations.**

The most visible symptom of Fusarium wilt is the presence of wilted and dying cotton plants in a field. Some plants may be stunted and the leaves may yellow between the veins (also known as interveinal chlorosis). Root-knot nematodes alone can cause wilting, but the synergistic effect with the Fusarium fungus is usually required to kill plants, unless the soil is extremely dry for prolonged periods. Fusarium-infected plants wilt even if soil moisture is adequate because of damage to the vascular system that carries water throughout the plant.

A preliminary diagnosis of Fusarium wilt can be made fairly easily in the field by slicing through the plant stem at a shallow angle to expose the vascular tissue. Fusarium wilt will cause a noticeable browning of the vascular tissue. This discoloration is the result of damage to the vascular tissue which prevents adequate flow of water and nutrients. If you **carefully dig up** the root system of wilting plants, you will also usually see significant galling caused by root-knot nematodes. To verify the diagnosis, submit a sample through your county agent to the UGA Plant Disease Clinic. You should also submit a soil sample for nematode assay to the UGA Extension Nematology Laboratory.

Plants affected by Fusarium wilt tend to be clustered in the field rather than randomly spaced. In fact, areas of the field where Fusarium wilt occurs will probably be consistent from year to year. This is because the fungal pathogen and the associated parasitic nematodes tend to be unevenly distributed in the field.

Additional information on Fusarium wilt in cotton can be found in University of Georgia Extension Bulletin 1143, "Cotton Diseases and Their Control." and "Cotton Nematodes and Fusarium Wilt", Leaflet L 82, 1996.

SECTION 6. BOLL ROT

Boll rots are caused by a complex of fungal and bacterial pathogens. Boll rot is unavoidable if cotton is subjected to prolonged periods of wetness and humidity late in the growing season. In Georgia, this can happen if a tropical storm or hurricane causes excessive rainfall, especially over a several-day period. In such situations, there is little a farmer can do to minimize losses to boll rots.

Actions that reduce humidity in the cotton canopy can help reduce the likelihood of a significant boll rot problem in the absence of inclement weather. Such practices include proper nitrogen fertilization to avoid rank vegetative growth, lower plant populations (plants/acre), timely defoliation and harvest, and the use of mepiquat chloride, a plant growth regulator which limits vegetative growth. These practices increase airflow through the canopy and reduce humidity around the lower bolls which makes the microclimate less conducive for boll rots. Adjusting planting dates so that bolls approach maturity later in the summer, when conditions are typically drier, can help. Neither fungicides nor bottom defoliation have proven effective for boll rot control. Plants with fewer bolls may have increased vegetative growth, which can increase humidity in the plant canopy thereby increasing boll rot problems. For additional information, refer to UGA Extension Leaflet 143, "Cotton Boll Rot."

Good insect control can reduce boll rot. Injury from insect feeding can increase boll rot by creating wounds where rot-inducing organisms can enter bolls and by causing plants to set fewer bolls. Also, proper insect control can promote better plant utilization of nitrogen, thus reducing excessive vegetative growth.

COTTON DISEASE CONTROL

Bob Kemerait, Extension Plant Pathologist

DISEASE	CHEMICAL	MOA	RATE PER ACRE ^a (38" Row Basis)	REI/PHI (Hours/Days)	REMARKS AND PRECAUTIONS
Seedling Diseases	<i>azoxystrobin</i> Quadris 2.08SC	11	5.5–11 fl oz	4 H/ 45D	Liquids give better coverage than granular or hopperbox treatments. Liquid fungicides should be applied in-furrow using two cone-type nozzle tips. Mount the first behind the seed-drop tube to treat the soil around seed; direct the second to treat soil as it falls into the seed furrow. Maximum rate is 27 fl oz/A/season.
	<i>prothioconazole</i> Proline	3	5.7–7.1 fl oz		
	ADDITIONAL SEED TREATMENTS				
	<i>azoxystrobin + fludioxonil + mefenoxam</i> DynastyCST		3.1–3.95 fl oz/cwt	24 H/ —	NOTE: These seed treatments are in addition to fungicide treatments that are already applied to the seed by the supplier.
	<i>chloroneb + metalaxyl</i> Delta Coat		8.75–11.85 oz/cwt		
	KodiakFL		0.5 fl oz/cwt		
	Kodiak HB (biological)		4 oz/cwt		
	System 3 (biological)		12 oz/cwt		
	<i>trifloxystrobin + metalaxyl</i> Trilex2000		2 fl oz/cwt		
<i>trifloxystrobin + metalaxyl + triademinol</i> Trilex Advanced		1.6 fl oz/cwt			

- a. In-furrow fungicide rates are presented on a per acre basis for cotton planted on 38" rows. To convert these rates to cotton planted on 36" rows, multiply the 38" rate by 1.05. To convert the rates to cotton planted on 40" rows, multiply the 38" rate by 0.95. To convert the rates from a per acre basis to a rate per 1000 feet of row, divide the 36" rate by 14.42, divide the 38" rate by 13.76, and divide the 40" rate by 13.07.
- b. Apply all liquids in 5–10 gal of water/A.

COTTON NEMATODE CONTROL

Bob Kemerait, Extension Plant Pathologist

NEMATOCIDE TREATMENT	RATE/ACRE	OZ/1000 FT OF ROW (38" row basis)	REI/PHI (Hours/Days)	REMARKS AND PRECAUTIONS
<i>abamectin + thiamethoxam</i> AVICTADuoCotton	Seed treatment		48 H/ —	
<i>aldicarb</i> AgLogic 15G	3.5–7lb			Apply granules in seed furrow and immediately cover with soil by mechanical means. In the States of AL, FL, GA, and SC, if a vulnerable soil is present and the water table is less than 25 feet below ground surface, do not apply within 700 feet of a drinking water well unless it is known or reasonably believed based upon authoritative sources that such wells are either cased to 100 feet below the ground level or a minimum of 30 feet below the water table. If it is not known whether the water table is greater than 25 feet below ground surface, assume that the water table is less than 25 feet below ground surface.
<i>aldicarb</i> AgLogic 15G sidedress application	5 lb			Side Dress Application: From 3 weeks after planting through first squaring. Side dress granules in a furrow that is 6–10" to one or both sides of plant row to a depth of 2–3". Adjust applications to minimize root pruning.
AERIS Seed-Applied System	Seed treatment			AERIS Seed-Applied System is a combination of <i>thiodicarb</i> (nematode control) and <i>imidacloprid</i> (thrips control) with the option of adding the TRILEX Advanced Seed-Applied System for additional control of seedling diseases. AERIS Seed-Applied System should only be considered for use in fields with low-to-moderate populations of plant parasitic nematodes. Maximum rate of 25.6 fl oz/100 lb of seed (de-linted seed only).
derived from the bacterium, <i>Burkholderia rinojensis</i> BLOST Nematicide 100	Seed treatment			The active ingredient is 'Heat Killed' <i>Burkholderia rinojensis</i> and spent fermentation media that contains enzymes and toxins that have broad spectrum activity on nematodes and activity on soil-dwelling insects.
<i>fluopyram</i> COPeO Prime	Seed treatment			COPeO Prime contains <i>fluopyram</i> for the management of nematodes affecting cotton.
<i>fluopyram</i> Velum	5.0–6.84 fl oz		12 H/ 30D	Velum is also labeled for suppression of Fusarium wilt. Velum will replace Velum Prime as Bayer's nematocidal. All Velum Total uses in Georgia will switch to the new Velum product. While there may be some Velum Total still available on-farm in 2021, there should not be any Velum Total sold commercially. Note that without the imidacloprid component, Velum will not control thrips.
<i>fluopyram + imidacloprid</i> Velum Total	14–18 fl oz		12 H/ 30D	Apply specified dosage in the following methods: 1) In-furrow spray during planting directed on or below seed; 2) Chemigation into the root-zone through low pressure drip or trickle irrigation. Do not apply more than 19 fl oz/A of Velum Total per year. Do not apply Velum Total within 30 days of harvest. Regardless of formulation or method of application, apply no more than 0.5 lb <i>imidacloprid</i> or 0.45 lb <i>fluopyram</i> active ingredient per acre per year (ai/A/year), including seed treatment, soil, and foliar uses.
Telone II ¹	3 gal	30 fl oz	5D Post Application/ —	Apply Telone II at least 7 days prior to planting by injecting 12" below final soil surface. Temik may be used at planting or as a side-dress following the use of Telone II. NOTE: Telone II is now labeled for at-plant application in Georgia for nematode control on cotton. Growers who choose to apply Telone II at plant must ensure that soil conditions are correct (see label) otherwise the at-plant fumigation may result in poor germination and plant stand.
Vydate C-LV	17 fl oz	1.24 fl oz	48 H/ 14D	Make one application between 2nd and 5th true leaf stage. Alternatively, sequential applications of Vydate C-LV may be made at 8.5–11 fl oz/A beginning at 2nd–5th leaf stage of growth followed by a second 8.5–11 fl oz/A applied 10–14 days later. Applications of Vydate C-LV typically follow use of Telone II or nematocidal seed treatments. Vydate C-LV is a supplemental application. Maximum rate is 102 fl oz/A/season.
<i>tioxazafen</i> Acceleron NemaStrike ST				Acceleron NemaStrike ST is a seed treatment nematocidal for use on cotton.

1. If Telone II is used for nematode control, you must use an additional chemical for thrips control.
2. AgLogic 15G applied at 3.5 lb/A is often recommended for insect management, but 3.5 lb/A will not provide sufficient nematode control in Georgia.

COTTON FOLIAR DISEASE CONTROL

Bob Kemeraït, Extension Plant Pathologist

FUNGICIDE TREATMENT	RATE/ACRE	REI/PHI (Hours/Days)	REMARKS AND PRECAUTIONS
<i>azoxystrobin</i> AzoxyStar	6–9 fl oz	— 45D	
<i>azoxystrobin</i> Quadris	6–9 fl oz	4H/ 45D	Maximum rate is 27 fl oz/A/season.
<i>azoxystrobin + benzobendiflupyr</i> (solatenol) Elatus	5–7.3 fl oz	12 H/ 45D	Do not apply more than 14.6 fl oz/A per season.
<i>azoxystrobin + difenconazole</i> Amistar Top	8–11.6 fl oz	— 0D	Do not apply more than two sequential applications before alternating to a fungicide with a different mode of action.
<i>difenoconazole + pydiflumetofen</i> Miravis Top	13.6 fl oz	12H/ 45D	
<i>flutriafol</i> Topguard	7–14 fl oz	12 H/ 30D	
<i>flutriafol + azoxystrobin</i> TopGuard EQ	5–7 fl oz	12H/ 45D	
<i>prothioconazole</i> Proline	5.0–5.7 fl oz	12H/	Do not make more than three total applications per season.
<i>pyraclostrobin</i> Headline	6–12 fl oz	12 H/ 30D	
<i>pyraclostrobin + fluxapyroxad</i> Priaxor	4–8 fl oz	12H/ 30D	Do not apply more than 24 fl oz/A per season.
<i>pyraclostrobin + metconazole</i> Twinline	7–8.5 fl oz	12 H/ 30D	Maximum rate is 26 fl oz/A/season.

PLANT GROWTH REGULATOR USE

The best “growth regulator” for cotton is good, early fruit set and retention, as this will generally deter excess vegetative growth. Therefore, nitrogen levels, soil moisture, insect control, plant population, and crop management influence the cotton plants’ ability to balance vegetative and reproductive growth. There are two ways to influence the plants’ vegetative/reproductive balance. An indirect influence would be timely applications of boron, which aids flowering and fruit set. As a management tool, growth regulators containing mepiquat are specifically used to reduce vegetative growth. Mepiquat is available in several formulations sold under the trade names of Pix, Pix Plus, Mepex, Mepex Ginout, Topit, Mepichlor, Pentia, and Stance among others. Mepiquat has a number of effects on cotton growth and development. The most consistent effect of mepiquat is the reduction of plant vegetative growth and shorter plants by shortening internode length. It also reduces leaf area in portions of the plant canopy where stem and leaf expansion are taking place. It controls growth in such a way that does not create carbohydrate stress in the plant.

Mepiquat applications are also often associated with a slight increase in early fruit retention and thus, contributes to a trend toward early maturity. Yield responses have been erratic and inconsistent. Slight increases, slight decreases, and no effect are prevalent in the volumes of research dealing with mepiquat. Yield advantages observed with mepiquat-containing products are most often linked to situations in which the product contributes toward increased harvest efficiency, improved insecticide/defoliant penetration through the canopy, hastened maturity (in later planted cotton), and retention of earlier-set larger bolls. Most conditions that would likely result in a positive response to mepiquat are not easily predictable, except for some problematic and/or irrigated fields that historically result in adversely tall plants. With the wide range of growth potential among our current modern varieties, it is important to understand the growth potential of any particular variety, and how the environment influences growth of a particular variety, before applying mepiquat. Slower growing earlier maturing varieties may seldom need aggressive PGR management (high rates, prebloom applications, etc.) depending upon the prevailing environment. However, the environment (i.e. rainfall or irrigation) dictates the likelihood of excessive growth more so than most of other factors. Field history often provides insight on the likelihood of excessive growth.

Mepiquat formulations which include the hormone kinetin (Mepex Ginout), or formulated as a pentaborate salt (Pentia) as opposed to a chloride salt (all others) have resulted in similar responses to other mepiquat-containing PGRs in UGA trials. Several recent small and large plot trials were conducted to evaluate Stance (a premix of mepiquat chloride and cyclanilide). This product is used at lower rates compared to other mepiquat-containing products. Recent experience with this product suggests that Stance, when used at appropriate application rates, has similar effects on plant growth and development, when compared to other mepiquat-containing products. Trials conducted in 2010 suggested that Stance applied at appropriate and recommended rates (usually 2.5 to 3 oz/a depending upon growth stage) may have milder effects on plant growth than the commonly used rates of other mepiquat-containing PGRs. Therefore, Stance may reduce risks of severe stunting due to hot or dry weather following application, especially for early maturing varieties or varieties that generally portray less aggressive growth.

Currently UGA data indicates that all mepiquat-containing products should be used at the same rates and timings, with the exception of Stance. *The use rate of Stance recommended by Bayer CropScience is 3 oz/A in all situations. This rate may be lowered to 2.5 oz/A if the first application is made prior to, or at the initiation of squaring.*

Even though mepiquat has been available for over 25 years, questions persist about how to use the product. Indications from the literature show that a given rate of mepiquat in a small plant leads to

more height/growth reduction than that same rate in a large plant. This is related to concentration -- the concentration of a given rate of mepiquat will be greater in a small plant and more dilute in a large plant. If the product is applied when vegetative growth is nearly complete, little effect on height occurs. After a leaf has fully developed and internodes have elongated, no amount of mepiquat can shrink them. Vigorous plants show less response (reduction in internode length, duration of growth control, etc.) than slower growing plants. In growth chamber studies in Mississippi, mepiquat had less effect on cotton grown at high temperatures (>95^oF) or on plants under drought stress. Therefore, the activity of mepiquat is greater within plants that are actively growing, with good moisture under warm, moderate temperatures.

Factors that must be considered when determining when and how much mepiquat to use include: (1) stage of plant growth, (2) rate of plant growth, (3) pest control and (4) anticipated plant growth (irrigation, drought, fertility). Because of the many variables, hard and fast rules regarding the rate and timing of mepiquat are not appropriate. Fields vary in growth. Weather varies by year/location, and thus, recommendations must be flexible.

In most irrigated fields, we can comfortably begin low rate applications (4 oz) at least by the second week of squaring and continue on a 14-day interval for three or four applications. Another common approach in irrigated conditions is to apply 8 to 12 oz at first bloom or just prior to bloom, with a subsequent treatment if needed at 8 to 12 oz two or three weeks later. The key to plant management for aggressive varieties may be making applications earlier, when the plant is 12 to 16 inches tall, especially in fields that frequently receive and retain moisture. In dryland situations, applications at, or just prior to, first bloom is usually a time to consider mepiquat at rates near 8 oz, if growth is vigorous. If aggressive growth continues, a follow up treatment may also be needed. These suggestions provide a framework upon which to base timing and rates.

A common error is to delay applications past the point where the product can provide its maximum benefit. If the intent is a single (or at most two) application program, growers should be targeting cotton in the 16 to 24 inch range. Applications that are not made until cotton reaches 30 inches often do not adequately control growth. Some varieties may not require aggressive use of mepiquat, while some may require multiple applications and higher rates depending upon the prevailing environment and moisture status. Therefore, it is very important for growers to closely monitor plant growth in all fields, and apply mepiquat accordingly, as every situation is different.

Late-season applications of mepiquat have received attention for several years. The theory behind these applications is that they will reduced vegetative growth at the time of cut-out thus channeling more energy into the development of late-season bolls. Current UGA research has not shown any yield advantage, nor any other advantage, resulting from mepiquat applied at this growth stage.

Optimal growth control should result in plant height that is harvest efficient while avoiding excessively tall plants that may result in lodging, severe delays in maturity, loss of critical fruit, or obstruction of spray applications. However plants should be sufficiently tall to support adequate fruiting sites for optimal yields while achieving full canopy closure. Any plant growth regulation strategy should attempt to slow terminal growth enough to allow the increasing developing boll load to restrain vigorous growth, with terminal growth ceasing at an optimal plant height. Plant growth regulation strategies that are too weak (late applications, low rates) may result in suboptimally tall plants if growth is vigorous, while aggressive strategies (early/multiple applications, high rates) may result in insufficient plant height if stress is encountered. Therefore, these decisions need to be made on a case-by-case basis.

Visit the UGA Cotton Webpage for information on PGR management of particular cotton varieties.

IRRIGATION

Although cotton is considered to be a relatively drought-tolerant crop, it is an excellent candidate for irrigation, due to its positive response to well timed irrigation and the climate variability we typically experience in the Southeastern Region. Irrigation is particularly important in areas that frequently have drought in July through August and on locations with sandy textured soils. It is commonly said that in the Coastal Plains we are never more the three or four days away from a drought, and based on our major soil types in the region that is true. Even though it typically appears that ample rainfall is received during the cotton production season this region of the southeast has periods of episodic drought that can cause significant yield reductions. It should be stressed that it is not necessarily about the amount of rain that is received, but the frequency and distribution of that rainfall that matters when it comes to producing high levels of yield. This is also true for irrigation, it is not necessarily about the total amount of irrigation applied, but that an ample amount is applied at the correct time. Irrigation may increase yields from a range of none in wet years to more than 800 lb/A, with increases of 200 to 400 lb/A being common. Irrigation should be supplemental to rainfall, as total reliance on irrigation in the absence of periodic rainfall would be difficult for some producers to achieve with system sizing and water supply. The most critical period of water requirement is during the bloom and boll maturation periods. At peak bloom, the plant can require up to about 0.3 inches of water per day but, factors such as available soil moisture in the profile, soil type and atmospheric conditions can increase or lower this need. Recent UGA research indicated that timely irrigation with moderate rates during squaring (period when potential fruiting sites are developing) may also have a strong influence on yields.

Many uncertainties exist as to how to properly schedule irrigation. While many of the recent cotton production seasons have had in excess of 20 plus inches of rain there are periods of drought during each season which cause yields to fall well below expectations in terms of yield and fiber quality. Careful consideration is advised during high rainfall or wet years as excessive irrigation can reduce yield potential, to in some cases below the level of the dryland crop. It is advised to implement a sound irrigation scheduling strategy during any year. Strategies may include the checkbook method, apps, and probably the most reliable and accurate means are with soil moisture sensors. The major take home point is to have at least one option of scheduling irrigation and multiple options are even better.

A recent publication developed by Cotton Incorporated, “Cotton Irrigation Management for Humid Regions”, is an excellent resource for growers that provides a broad, general overview of cotton irrigation for our region. This publication is available online at:

<http://www.cottoninc.com/fiber/AgriculturalDisciplines/Engineering/Irrigation-Management/>.

In the past, irrigation of cotton prior to blooming was initiated when plants began to wilt or exhibited stress by mid-day. However, research has indicated that once cotton begins to wilt, it has already been under physiological stress for some time and yield potential has been lost. Prior to bloom cotton will utilize 0.75 to 1 inch of water per week, which is most important during squaring (7-leaf stage to first bloom). Thus, under hot and dry early season conditions to optimize yield potential the crop should be irrigated at this amount prior to the signs of stress. It should also be recognized however, that abundant moisture magnifies vegetative growth problems when excessive nitrogen is available and/or insect control is insufficient. It is encouraged that producers follow the UGA Checkbook method developed from 2001-2016 historical average evapotranspiration data (Table 8 and Figure 15). After first bloom, producers trying for high yields are encouraged to irrigate as needed to supply the quantities of water listed in Table 9. Rain gauges should be used to measure the water received from rain and the amount supplied by irrigation. An example of how to use these values is included below.

Table 8. UGA Checkbook Cotton Irrigation for Full Season

Cotton Irrigation Schedule				
Growth Stage	Days after Planting	Weeks after Planting	Inches per Week	Inches per Day
Emergence	1 - 7	1	0.04	0.01
Emergence to First Square	8 - 14	2	0.18	0.03
	15 - 21	3	0.29	0.04

Harvest	162 - 168	24	0.00	0.00
	169 - 175	25	0.00	0.00

Figure 15. Weekly UGA Checkbook Cotton Irrigation for Full Season

Table 9. Cotton Irrigation Schedule Suggested for High Yields

Crop Stage	Inches/Week	Inches/Day
Week beginning at 1 st bloom	1.0	0.15
2 nd week after 1 st bloom	1.5	0.22
3 rd week after 1 st bloom	2.0	0.30
4 th week after 1 st bloom	2.0	0.30
5 th week after 1 st bloom	1.5	0.22
6 th week after 1 st bloom	1.5	0.22
7 th week and beyond	1.0	0.15

Examine the crop during the 7th week and 8th week of bloom to determine if irrigation should be terminated. Additional irrigation may be needed on deep sands, during hot and dry weather, and in windy conditions. It is generally recommended that irrigation be terminated when a noticeable number of bolls have opened, especially when the majority of harvestable bolls are located on lower plant nodes. However, if the majority of the targeted harvestable bolls remain relatively immature when only a few lower bolls begin to open, irrigation may still be required for a short time. Irrigation termination can be a difficult decision. A final irrigation event is often applied when the crop begins to open. Commonly, NO additional irrigation is applied once the crop reaches 10% open boll to minimize problems with boll rot, hard lock, light spot, and other fiber quality issues. Common sense factors for irrigation scheduling and recommended application amounts include prevailing weather patterns and predictions, available soil moisture, and time of year.

Growers with intensely managed production programs that are already harvesting 2-bale yields and are striving for 3-bale-plus yields on part of their crop may want to increase the amount of water supplied by irrigation if water availability appears to be a limiting factor. Additionally, as stated above over-irrigating can cause yield losses and excessive vegetative growth. Growers attempting to achieve

high yields should consider implementing a very robust irrigation management plan, which could include the use of advanced irrigation scheduling tools that include but are not limited to consultants, soil moisture sensors, and online or smartphone app schedulers. A publication which contains more in-depth information about placement and interpretation of data on soil moisture sensors, is located here:

https://cottoncultivated.cottoninc.com/research_reports/placement-and-interpretation-of-soil-moisture-sensors-for-irrigated-cotton-production-in-humid-regions/

Irrigation Example

- Step 1. The soil type of the field is a Tifton loamy sand. In Table 10, the average available water holding capacity is 1.0 inches/ft. Assuming a rooting depth of 2 feet, the total available water is 2.0 inches (2 ft x 1.0 inches/ft).
- Step 2. If the cotton crop is determined to be during the 3rd week of bloom. From Table 9, the daily water use by the crop is 0.3 inches/day.
- Step 3. Determine replacement water amount by setting the lower allowable limit of available water in the profile. For this example, we will use a typical value of 50% allowable depletion (i.e. only 50% of the water in the root zone will be allowed to be depleted). Therefore, 1.0 inches of water will be required to replace the water used (2.0 inches x 0.50).
- Step 4. Determine the amount of irrigation to apply by dividing the amount to be replaced by an irrigation efficiency from Table 11. (There are always losses between water pumped and water actually reaching the crop, such as evaporation, drift, etc.). In this example, we will assume a fairly new center pivot with optimal efficiency, at 88%. Thus, amount to apply = 1.0 inches / 0.88 = 1.14 inches.
- Step 5. Determine the frequency of irrigation by dividing the amount of water replaced by water use per day. For example, frequency = 1.0 / 0.3 = 3.3 days.
- Step 6. In this example, it would be necessary to apply 1.14 inches every 3 days to maintain 50% available water in the Tifton loamy sand soil profile for cotton in the 3rd week of bloom. Any rainfall received would be subtracted from the amount to apply.

It is important to note that typically an irrigation application amount greater than 0.75 inches results in runoff in most soil types in Georgia. This means that you will lose any additional water over 0.75 inches, thus it is recommended that you not exceed this amount in any one single application. This is also the case with rainfall. High intensity rainfall events often become runoff too, and it is recommended that a producer carefully manage for rainfall. It is more beneficial for the crop if the required 1.14 inches were split into two applications of 0.57 inches every 1.5 days. If you have a pivot so large that it cannot make a round through the field in the calculated split time it is recommended that you apply the minimum amount required for the pivot to travel around the field as quickly as possible, and repeat this step as often as needed to reach required irrigation amounts. In most cases more frequent irrigation applications with lower rates are recommended. However, the rates still need to be high enough so that they can reach and infiltrate into the soil.

Irrigation intervals for most of the season will be 3 to 4 days for coarse textured sand, 4 to 6 days for more productive loamy sand and sandy loam, and 5 to 8 days for fine textured sandy loam or clay soils. A 4 to 6 day interval will fit a majority of the situations.

Table 10. Examples of Available Water Holding Capacities and Infiltration Rates of Soils in the Coastal Plain of Georgia.

Soil Series	Description	Intake (Inches/Hr) for Bare Soil*	Available Water Holding Capacity (inches/Ft)
Faceville	Sandy Loam, 6-12” Moderate intake, but rapid in first zone	1.0	1.3
Greenville			1.4
Marlboro			1.2-1.5
Cahaba	Loamy Sand, 6-12” Loamy subsoil, rapid in first zone, moderate in second	1.2	1.0-1.5
Orangeburg			1.0-1.3
Red Bay			1.2-1.4
Americus	Loamy Sand, 40-60” Rapid permeability	2.0	1.0
Lakeland			0.8
Troup			0.9-1.2
Norfolk	Loamy sand, 12-18” Rapid permeability	1.3	1.0-1.5
Ochlocknee			1.4-1.8
Dothan	Loamy sand and sandy loam, 6-12” Moderate intake	1.0	1.0-1.3
Tifton			0.8-1.0
Fuquay	Loamy sand, 24-26” Rapid permeability in first zone, moderate in second	1.5	0.6-0.8
Lucy			1.0
Stilson			0.9
Wagram			0.6-0.8

* Increase soil infiltration rate in field where conservation tillage methods are used.

Table 11. Examples of Application Efficiency Values for Various Irrigation Systems.

Irrigation System Type	Application Efficiency (%)	
	Attainable	Expected
Center Pivot w/ Impact Sprinklers	85	75-85
Center Pivot w/ Spray-type Sprinklers	95	75-95
Lateral Move w/ Spray-type Sprinklers	95	75-95
Subsurface Drip	95	70-95
Micro-Spray	95	70-95
Trickle	95	75-95
Subsurface Drip	95	70-95
Moving Big Gun	75	60-75

Irrigation Scheduling

The moisture balance or “Checkbook” method of scheduling described above is a relatively straightforward means of determining WHEN and an estimated amount of HOW MUCH to irrigate. This method helps a grower keep up with an estimated amount of available water in the field as the crop grows. The objective is to maintain a record of incoming and outgoing water so that an adequate balanced amount is maintained for crop growth. Other methods of irrigation scheduling include more advanced methods or software such as Irrigator Pro (USDA, www.irrigatorpro.org), soil moisture

sensors from companies such as Irrrometer, Meter, AquaSpy, AquaCheck, etc., the SmartIrrigation Cotton App (www.Smartirrigationapps.org) and the UGA EASY Pan (a simplified pan evaporation device). These devices provide near real-time readings of either soil moisture content or soil water tension in the root zone and can identify when water is needed to replenish the root zone. Soil moisture sensors coupled with a sound irrigation strategy will typically provide the highest yield and water-use efficiency levels when compared to other methods because they are providing current readings and current crop water status, while other methods may just be estimates. Research results have shown that the checkbook method, even though most conservative, is not necessarily the most economically feasible method. Especially during years with higher levels of rainfall the checkbook method tends to reduce yields if not properly managed.

As stated earlier, growers with high yield goals should consider implementing a robust irrigation management plan. However, the grower must evaluate if the implementation of this plan is feasible for their operation. Based on the level of interest the grower should decide if they want to implement a simple plan that they can manage themselves or if they want to go more advanced and either hire a full-time employee for irrigation management or hire a consultant to provide recommended irrigation timing and amounts. This decision will be related to farm size, crop produced, and grower investment. Irrigation scheduling does take time, and growers are cautioned against implementing a plan without being properly prepared.

Knowing how aggressive your cotton variety grows and how well it responds to plant growth regulators is important. Keep in mind to never control or slow plant growth with irrigation applications. Apply water according to the plant needs and available soil moisture and let the PGR do its job.

DEFOLIATION

Cotton defoliates much easier when a good boll load has been obtained and available soil nitrogen is nearly depleted by the crop. At cutout, a mature crop is considerably easier to defoliate than one that maintains vigorous vegetative growth and fruiting into harvest time.

Harvest aid products perform several functions, the most important being defoliation, regrowth suppression, and boll opening. Removal of juvenile growth (late season immature foliage) and desiccation of weeds are functions also needed in certain situations. Of the many harvest aid chemicals, none will perform all these functions under all conditions. As a result, combinations of products are generally recommended and are frequently used, with adjustments in rates and product selection based on crop condition, temperature, calendar date, and equipment availability.

Refer to the tables below: Cotton Defoliation / Harvest Aid Options (as seen in the 2021 Pest Management Handbook) below for information about rates and combinations of harvest aids.

Timing of Defoliation Timing of defoliation is critical to insure optimum yield and fiber quality. Several factors can be used to determine the proper time for harvest aid application. The first is the traditional method of counting open and unopen bolls. Defoliation should proceed when least 60 to 75 percent of bolls are open. This method focuses primarily on the “open” portion of the bolls while ignoring the “unopen” portion, which is also important. A second indicator involves slicing bolls with a sharp knife. Bolls are considered mature--and ready for harvest aid applications--when bolls cannot be sliced without "stringing" the lint. In addition, bolls are mature when the seed embryo contains only tiny folded leaves (no "jelly" within the developing seed) and the seedcoat begins to turn yellow or tan. A final method utilized to determine crop maturity is counting nodes above cracked boll (NACB). NACB is determined by counting the number of nodes separating the uppermost first position cracked boll and the uppermost boll that is expected to be harvested. Once the NACB has reached 4 it is generally safe to apply harvest aids. In some cases, when plant populations are low, a NACB of 3 maybe mor appropriate. Growers shoul understand that each method of determining defoliation timing considers different plant characteristics, therefore the use of a combination of these methods would more accurately depict maturity of plants and provide a better indication for optimal defoliation timing. The figure on the right shows predicted percent open bolls to NACB (60% = 4.1 NACB).

Relationship between NACB & % Open Bolls (Bednarz et al. 2002)

Fig. 1. Nodes from the uppermost first sympodial position cracked boll to the uppermost harvestable boll (NACB) vs. percent open boll in harvest timing studies conducted at the University of Georgia Coastal Plain Experiment Station in 1998, 1999, and 2000. **Denotes significance at the $P = 0.01$ level.

% Open Bolls	NACB
30	7.3
40	6.2
50	5.2
60	4.1
70	3.1
80	2.0
90	1.0
100	0

Harvest Aid Functions

There are four basic functions of harvest aids when applied to cotton. Each process may or may not be required to prepare cotton harvest. An understanding is needed of these processes in order to properly determine products and rates to be chosen.

1. Removal of Mature Foliage
2. Removal of Juvenile Foliage
3. Boll Opening
4. Regrowth Suppression

The first two functions are considered to be involved with defoliation. Defoliation or leaf abscission is a natural plant process. The problem is this natural leaf drop does not occur simultaneously throughout the plant canopy, or in time to effectively facilitate mechanical harvest. Therefore, producers must manipulate the plant to drop its leaves in a relatively short period of time.

While the leaf abscission process is quite complex, it can be simplified as being governed by two major hormones within the plant, auxin and ethylene. Auxin is a growth-promoting hormone that stimulates leaf growth and development. Ethylene can be classified as a senescence or ripening hormone that causes leaf drop. Leaves fall from the plant once ethylene moves from the leaf blade to the base of the petiole and stimulates the formation of an abscission layer. The amount of auxin or

ethylene present in the leaves of the cotton plant is related to leaf age. Younger leaves have a more elevated level of auxin, while older leaves have lower levels of auxin and higher levels of ethylene. This is why older leaves are more conditioned for defoliation than younger leaves. Furthermore, because of the hormone balance of younger leaves, low rates of harvest aids often have no effect, and higher rates may actually kill the leaf, leading to desiccation and leaf sticking. Eventually, almost all the leaves on a cotton plant age so they will abscise naturally. However, producers can manipulate these hormone levels so all the leaves abscise at the same time. When harvest-aids are applied ethylene levels artificially increase so the abscission process begins.

All cotton harvest-aids can be classified into two modes of action, herbicidal and hormonal. Herbicidal harvest-aids injure the leaf, stimulating the production of ethylene (Tribufos [Folex] and PPO Inhibitors [Aim, ET, Blizzard, etc.]). Hormonal harvest-aids increase the ethylene concentration in the leaves without causing any injury (Ethephon [various brands] and products containing thidiazuron [Dropp, Freefall, etc.]). Product selection and application rates should be adjusted to match environmental conditions as they change during the harvest season in order to reduce occurrence of leaf desiccation.

Defoliant Applications

Most harvest aid materials do not translocate or move very far within the plant. Therefore, application coverage is important. To ensure adequate foliar coverage use the proper spray pressure, ground speed and nozzle size in order to apply the desired spray volume in accordance of label instructions.

WATER VOLUME CAN SIGNIFICANTLY IMPACT OVERALL PERFORMANCE, THE MORE WATER THE BETTER (SHOOT FOR 15 GPA)

Be sure to consider harvest when making defoliant applications and treat enough acres to anticipate harvesting the crop 10 to 14 days after application. Leaf drop should start in about four days and be complete in about 10 days. Rainfall occurring after applications can affect defoliant activity. Be sure to consider weather forecasts when making applications and pay attention to rain-free periods of particular products. Thidiazuron is of particular concern, since it requires a 24-hour rain-free period. Information on particular products and rain-free intervals, optimum temperatures for activity, and relative product performance can be found in the 2021 Mid-South Cotton Defoliation Guide (by T. Raper, B. Pieralisi, D. Miller, D. Stephenson, M. Foster, T. Sandlin, S. Brown, and B. Robertson) at https://news.utcrops.com/wp-content/uploads/2021/09/W376_2021.pdf.

In 2016, issues regarding adequate defoliation occurred when proper products, rates and applications were implemented. Every situation is different, but many of these cases were related to the dry conditions followed by some rainfall from the tropical systems resulting in a “dryland switch” which prevented defoliant from reaching deep into the canopy. Where excessive regrowth has already occurred, defoliation can be difficult and may require follow-up applications (or preconditioning). In other cases, the dry conditions affected the effectiveness of defoliants (especially hormonal) as plants were suffering from extreme moisture deficit stress. In either case, normally excellent treatments were less than adequate, and show examples of why time should be spent assessing the condition of the crop and the effectiveness of defoliants each year to ensure desired results.

Table 12. Rain-free period for selected cotton defoliant.

Product	Common Name	Rain-free Period¹	Company
Aim	carfentrazone-ethyl	6 to 8 hours	FMC Corporation
Display	carfentrazone + fluthiacet	6 to 8 hours	FMC Corporation
Boll Buster	ethephon	6 hours	Loveland Products, Inc.
Boll'd	ethephon	6 hours	Winfield Solutions, LLC.
Ethephon 6	ethephon	6 hours	Arysta U.S.A.
Setup 6SL	ethephon	6 hours	ADAMA Group
Super Boll	ethephon	6 hours	Nufarm Americas Inc.
Finish 6 Pro	ethephon + cyclanilide	6 hours	Bayer CropScience
Resource	flumiclorac	1 hour	Valent U.S.A.
Blizzard	fluthiacet-methyl	1 hour	Chemtura
ET	pyraflufen ethyl	1 hour	Nichino America
Sharpen	saflufenacil	1 hour	BASF
Defol 5	sodium chlorate	24 hours	Drexel
Daze 4SC	thidiazuron	24 hours	Winfield Solutions
Freefall SC	thidiazuron	24 hours	Nufarm Americas

Folex	tribufos	1 hour	Amvac Chemical

¹Expected rain-free periods are estimates only and other conditions, including temperature, moisture and crop status may play a role in product performance. See specific labels for more information.

COTTON DEFOLIATION / HARVEST AID OPTIONS

The following are basic guidelines for harvest aid application. Rates indicated are amount per acre. Specific rates should be adjusted according to temperature, humidity, day-length, plant leaf condition and maturity, expected weather, and desired effects such as defoliation, regrowth control, boll opening, and/or weed control. Defoliants should be applied in a minimum spray volume of 5 gal/A by air and 10–20 gal/A by ground.

Camp Hand and Stanley Culpepper, Extension Agronomy and Weed Science

Reduced performance issues are often related to low spray volume and poor canopy penetration. Fields should fit into one of the following categories based on temperature and harvest aid function. Preparing cotton for harvest is often difficult and is influenced by many factors, therefore the guidelines below should be considered as basic recommendations. Always observe label restrictions before using cotton harvest aids.

HARVEST-AID FUNCTION	HERBICIDE	BROADCAST RATE/ACRE (The rates below are given in the broadcast amount per acre unless otherwise noted)			REMARKS AND PRECAUTIONS
		EARLY-SEASON (highs 90°F plus, lows 70°F plus)	MID-SEASON (highs 80–89°F, lows 60–70°F)	LATE-SEASON* (highs below 80°F, lows below 60°F)	
Defoliation Only (combinations provide more consistent defoliation than a single product)	<i>carfentrazone ethyl</i> Aim 2.0EC	0.75–1 fl oz	0.75–1 fl oz	1 fl oz	Add non-ionic surfactant at 0.25% v/v during early-season and with 1 oz/A rate; add COC for 0.75 oz rate mid-season. The potential for leaf sticking is greater during periods of high temperatures.
	<i>carfentrazone ethyl</i> + <i>fluthiacet-methyl</i> Display 2.05EC	Up to 1 fl oz	Up to 1 fl oz	Up to 1 fl oz	Limited data, adhere to label restrictions, use precaution.
	<i>flumiclorac</i> Resource 0.86EC	4–6 fl oz	4–6 fl oz	4–6 fl oz	Add crop oil at 1–2 pt/A. Limited data, use precaution. The potential for leaf sticking is greater during periods of high temperatures. Label allows rate up to 8 fl oz.
	<i>fluthiacet-methyl</i> Blizzard 0.91EC	0.5–0.6 fl oz	0.5–0.6 fl oz	0.5–0.6 fl oz	Add crop oil at 1 pt/A. Limited data, use precaution.
	<i>pyraflufen ethyl</i> ET 0.208EC	1.5 fl oz	1.5 fl oz	1.5 fl oz	Add crop oil at 0.5% v/v early-season and increase rate to 1% in cooler conditions. The potential for leaf sticking is greater during periods of high temperatures. Label allows rate up to 2.75 oz/A.
	<i>sodium chlorate</i> Defol SSL, others	3 lb ai	4 lb ai	4 lb ai	Apply to mature foliage only. Do not mix with products containing <i>tribufos</i> or <i>ethephon</i> . Label allows a maximum use rate of 6 lb ai.
	<i>tribufos</i> Folex 6EC, others	1–1.5 pt	1–1.5 pt	X	Reduce rate to 1.25 pt if above 94°F.
	<i>thidazuron</i> + <i>diuron</i> Ginstar 1.5EC, others	X	X	8–10 oz	Limited data are available.
	<i>tribufos</i> Folex 6EC + <i>paraquat</i> Gramoxone 3S, others	X	X	1.5 pt + 2–8 oz	May cause crop desiccation and damage to unopened bolls.

*Late-season defoliations may require a preconditioning treatment to be successful (see preconditioning section). X = denotes product not suggested during those environmental conditions.

HARVEST-AID FUNCTION	HERBICIDE	BROADCAST RATE/ACRE (The rates below are given in the broadcast amount per acre unless otherwise noted)		REMARKS AND PRECAUTIONS
		EARLY-SEASON (highs 90°F plus, lows 70°F plus)	MID-SEASON (highs 80–89°F, lows 60–70°F)	
Regrowth control and defoliation	<i>thidiazuron</i> Dropp 4SC, others	3.2 fl oz	3.2 fl oz	For maximum regrowth control. <i>Thidiazuron</i> is sensitive to wash-off when rain occurs within 24 hours and may be vulnerable through 12 hours after application. Addition of <i>tribufos</i> (4–8 oz) or <i>ammonium sulfate</i> (2 lb/A) enhances rain fastness.
	<i>thidiazuron</i> + <i>diuron</i> Ginstar 1.5EC, others	6.4–8 fl oz	6.4–8 fl oz	Limited data are available on these products. Regrowth control is minimal when these products are applied at rates below 6.4 fl oz.
	<i>thidiazuron</i> Dropp 4SC, others + ONE OF THE FOLLOWING:	1.6–2.5 fl oz +	2–2.5 fl oz +	Label allows rate to be increased to 3.2 fl oz.
	<i>carfentrazone ethyl</i> Aim 2.0EC	0.75 fl oz	0.75–1 fl oz	Add non-ionic surfactant at 0.25% v/v during early-season and with 1 oz/A rate; add COC for 0.75 oz rate mid-season. The potential for leaf sticking is greater during periods of high temperatures.
	<i>tribufos</i> Folex 6EC, others	4–16 fl oz	1 pt	These combinations may cause “leaf sticking” when temperatures exceed 94°F, when combined with spray adjuvants, or when calibration errors occur. Consider reducing higher rates of <i>tribufos</i> by 10–20% when temperatures exceed 94°F. Maximum use rate when mixed with Dropp is 24 fl oz/A.
	<i>carfentrazone ethyl</i> + <i>fluthiacet-methyl</i> Display 2.05EC	upto 1 fl oz	upto 1 fl oz	Limited data, adhere to label restrictions, use precaution.
	<i>flumiclorac</i> Resource 0.86EC	4–6 fl oz	4–6 fl oz	Add crop oil at 1 pt/A during early-season and 1–2 pt/A during mid-season. Limited data, use precaution. Label allows rate up to 8 fl oz.
	<i>fluthiacet-methyl</i> Blizzard 0.91EC	0.5–0.6 fl oz	0.5–0.6 fl oz	Add crop oil at 1 pt/A. Limited data, use precaution. The potential for leaf sticking is greater during periods of high temperatures.
	<i>pyraflufen ethyl</i> ET 0.208EC	1.5 fl oz	1.5 fl oz	Add 0.5% v/v crop oil during early-season and 1% during mid-season. Label allows rate up to 2.75 fl oz.

PRECONDITIONING

Fields with a dense canopy of foliage and significant numbers of green bolls may require two applications. The goal is to remove much of the foliage with an initial application, exposing un-open bolls to sunlight and improving air circulation within the canopy. The follow-up application should be made 7–10 days later when sufficient leaf drop has occurred to allow spray coverage with boll opening products containing ethephon. However, premature preconditioning or defoliation may increase the risk of halting development of younger or immature bolls, rendering them unharvestable.

TREATMENT	HERBICIDE	BROADCAST RATE/ACRE	REMARKS AND PRECAUTIONS (The rates below are given in the broadcast amount per acre unless otherwise noted)
Initial Preconditioning Treatment	<i>carfentrazone-ethyl</i> Aim 2.0EC	1 fl oz	Add 1%v/v crop oil.
	<i>carfentrazone-ethyl+ fluthiacet-methyl</i> Display 2.05EC	up to 1 fl oz	Limited data, adhere to label restrictions, use precaution.
	<i>ethephon</i> Prep 6SC, others	0.67–1.33 pt	
	<i>flumiclorac</i> Resource 0.86EC	4 fl oz	Add 1–2 pt crop oil. Label allows rate up to 8 fl oz.
	<i>fluthiacet-methyl</i> Blizzard 0.91EC	0.5–0.6 fl oz	Add 1 pt crop oil.
	<i>pyraflufen ethyl</i> ET 0.208EC	0.3–0.75 fl oz	Add 0.5%v/v crop oil when temperatures are above 90°F. Add 1%v/v crop oil when temperatures are 89°F or below.
	<i>tribufos</i> Def/Folex 6EC	0.5–1.25 pt	
Follow-up Treatments	Should include products containing ethephon with harvest aid mixtures listed in the previous table.		

HARVEST AID WEED MANAGEMENT

Camp Hand and Stanley Culpepper, Extension Agronomy and Weed Science

HERBICIDE	BROADCAST RATE/ ACRE	REMARKS AND PRECAUTIONS (The rates below are given in the broadcast amount per acre unless otherwise noted.)
<i>carfentrazone-ethyl</i> Aim 2.0EC	1 fl oz	Add 1% v/v crop oil. Effective on morning glory, coffee senna, and tropical spiderwort.
<i>carfentrazone-ethyl + fluthiacet-methyl</i> Display 2.05EC	upto 1 fl oz	Limited data, adhere to label restrictions, use precaution.
<i>glyphosate</i> Roundup Powermax 3 5.88S, others	upto 2.5 pts	Use in combination with defoliant.
<i>paraquat</i> Gramoxone 3S, others Gramoxone Inteon 2S	1–4 fl oz 3–5 fl oz	Use in combinations with standard defoliation applications. May cause crop desiccation and damage to unopened bolls.
<i>pyraflufen ethyl</i> ET 0.208EC	1.5 oz	Add 0.5% v/v crop oil when temperatures are above 90°F. Add 1% v/v crop oil when temperatures are 89°F or below. Effective on morning glory. Label allows rate to be increased to 2.75 fl oz/A.
Follow-up Treatments Desiccants <i>paraquat</i> or <i>sodium chlorate</i>	See Desiccants for Cotton Harvest Preparation (below).	

DESICCANTS FOR COTTON HARVEST PREPARATION

Camp Hand and Stanley Culpepper, Extension Agronomy and Weed Science

DESICCANT	FORMULATION (lb ai/gal)	BROADCAST RATE/ ACRE (amount of formulation)	SPRAY VOLUME (gal/A)		REMARKS AND PRECAUTIONS (The rates below are given in the broadcast amount per acre unless otherwise noted.)
			GROUND	AIR	
<i>paraquat</i>					For addition to defoliant mixtures in cotton at least 85% open. Improves activity in colder, late-season conditions. May cause crop desiccation and damage to unopened bolls.
Firestorm	3	5.4 fl oz	10–20	5	
Gramoxone Inteon	2	3–5 fl oz	10–20	5	
Gramoxone Max	3	1–4 fl oz	10–20	5	
Parazone	3	5.4 fl oz	10–20	5	
<i>paraquat</i>					For desiccation of weeds and cotton regrowth after defoliation. Add surfactant at 1–2 qt/100 gal of spray solution. Be prepared to harvest in a timely manner (3 to 5 days ideally) to minimize bark problems. May cause crop desiccation and damage to unopened bolls.
Gramoxone Max	3	5.5 oz–1.5 pt	10–20	5	
Firestorm	3	0.7–1.3 pts	10–20	5	
Parazone	3	0.7–1.3 pts	10–20	5	
Gramoxone Inteon	2	1–2 pt	10–20	5	
<i>sodium chlorate</i>	4–6	3–6 lb ai	10–20	5–10	

PERFORMANCE RATING OF HARVEST AIDS BY FUNCTION

Camp Hand and Stanley Culpepper, Extension Agronomy and Weed Science

CHEMICAL NAME	FUNCTION				
	REMOVAL OF MATURE FOLIAGE	REMOVAL OF JUVENILE FOLIAGE	BOLL OPENING	REGROWTH SUPPRESSION	WEED DESICCATION
<i>ethephon</i> (Numerous brands)	F–G	F	E	P	P
<i>ethephon + urea sulfate</i> First Pick	G	G	E+	P	F
<i>ethephon + cyclanilide</i> Finish 6 Pro	G–E	F–G	E+	F	P
<i>paraquat</i> Gramoxone Max, Gramoxone Inteon, Parazone, Firestorm	F	F	P–F	P	G
<i>PPO inhibitors</i> Aim, ET, Resource, Blizzard	G	F	P	P	F
<i>sodium chlorate</i>	F	P	P	P	F–G
<i>thidiazuron</i> (Numerous brands)	G–E	G	P	G–E	P
<i>thidiazuron + diuron</i> (Numerous brands)	G–E	G	P	G–E	P
<i>tribufos</i> Def/Folex	G–E	P–F	P	P	P

P—Poor, F—Fair, G—Good, E—Excellent

UGA “THREE-WAY” DEFOLIATION MIXTURE RECOMMENDATIONS BY TEMPERATURE

Camp Hand and Stanley Culpepper, Extension Agronomy and Weed Science

SEASON (TEMPERATURES)	ETHEPHON (PREP 6SC)	THIDIAZURON (DROPP 4SC)	TRIBUFOS (FOLEX 6EC)
	BROADCAST RATE/ACRE		
Early Season (highs >90° F, lows >70° F)	21–24 fl oz	1.6–3.2 fl oz	6–12 fl oz
Mid-Season (highs 80–89° F, lows 60–70° F)	24–32 fl oz	2–2.3 fl oz	8–12 fl oz
Late-Season (highs <80° F, lows <60° F)	32–42 fl oz	X	16–20 fl oz

Ethephon—Higher rates necessary with cooler temperatures to increase boll opening.

Thidiazuron—Increase rates for greater regrowth potential, less activity when lows are less than 65°F for 3 days.

Tribufos—Higher rates necessary for cooler temperatures, however too high can desiccate. X = denotes product not suggested during these environmental conditions.

HARVESTING

To do a good job, pickers must be in top condition before they go to the field. Replace any excessively worn or damaged spindles. The alignment and adjustment of spindles to moisture pads and doffers make a considerable difference in the efficiency of a cotton picker. Improperly adjusted spindles will allow some of the cotton to remain on the spindle, causing spindle twist and lower both quality and harvesting efficiency. A well-adjusted picker and operation speed will pick cotton with a minimum amount of trash, particularly bark. Picking units and basket grates should be cleaned each time the basket is dumped. The accumulated trash and low-quality fiber should be discarded and not mixed in with the good cotton.

Start pickers after dew dries and stop when dew forms. Use a moisture meter to check the seed cotton moisture. If one is not available, bite the seed. If they crack, the moisture is probably low enough for harvesting. Cotton (lint, seed and trash combined) with a moisture content of 12 percent or lower can generally be harvested and stored satisfactorily. Keep harvested seed cotton dry.

Modules

Several factors have an impact on the effectiveness of the module system. The most critical is moisture. As stated in the previous section, cotton should be harvested at or below 12 percent moisture. Wet cotton placed in a module lowers grades and creates serious ginning problems, in addition to potentially causing module fires. While the gin process involves drying, gins are mainly designed to remove moisture from lint not from seed. Wet, soft seed greatly reduces gin efficiency and may clog equipment. Cotton with excessive seed moisture may require the gin operator to pass the cotton through the drying system more than once, lowering ginning rate and increasing ginning costs.

Another major factor in the ability of a module to properly store seed cotton is the construction of the module. The tighter the module is packed, the better it sheds rainfall and the less seed cotton is lost during storage, loading and hauling. Modules should contain approximately 14 bales or 21,000 lb of seed cotton. Making modules too large causes handling problems. The top should be rounded so that water sheds after the module is covered. Depressions in which water can collect are sure to cause problems.

Site selection is another important aspect of the moduling system. In Georgia, many fields are not well suited to module placement, so planning should be done before picking begins. If custom operators are used, the responsibility of site selection and preparation should be discussed.

Placement - Place modules where water will drain away from the module. Do not place modules at the bottom of water ways. The site should be free of gravel, stalks, and long grass. Prior to placement of modules stalks should be mowed and removed. Grassy areas should also be mowed and clippings removed. This may not seem important; however, grass or bark discounts can more than pay for time spent on site preparation. If possible, place modules in a north/south position so the sun will hit both sides during the day. Do not build modules in one location in the field and move to another. Each time a module is moved, it loses its firmness and shape.

Handling - Place modules on a firm surface accessible to trucks in wet weather. Do not till the soil on the truck approach side of the module. The surface in front of the module needs to be firm for the module hauler to retrieve the module without stretching it. Leave enough room in front of the module for the module hauler to get straight with the module for loading. Place approximately 14 bales in the module. An excessive amount of cotton will cause a truck to be overweight, is hard on loading mechanism, and may contact the top of the truck.

Monitoring and Managing Modules

1. Record and monitor the temperature of modules for the first 7 days. If a temperature rise of 20° F or a temperature of 120° F is reached, gin the module as soon as possible.
2. If a storm occurs, check module tarps and remove any water that has collected on top of the module cover.
3. Check tarps for holes and tears. Replace any defective tarp.

Yield Monitor and New Technology

Currently, there are two types of cotton yield monitors (John Deere and Ag Leader) available on the cotton pickers, however the Ag Leader yield monitor is no longer offered for purchase. A yield monitor can help identify low and high yield areas (spatial yield variability) within a field and how management practices that may be limiting yield can be changed to maximize productivity across the whole field. Yield data from an uncalibrated yield monitor can provide misleading or false information about yield variability, therefore it is critical to properly setup and calibrate the yield monitor prior to harvest. Remember that yield data quality is only as good as the calibration so make sure to spend time in properly calibrating the yield monitor. A timely and thorough pre-harvest check can minimize downtime and technology issues during the harvest. Make sure that mass flow sensors are clean and free of any debris or obstructions, wiring harnesses are not damaged and connected properly, and all other sensors (header height, GPS and in-cab display) are installed and functioning correctly. Regular checks on yield monitor functioning and yield data should be performed during harvest to avoid recording erroneous data. Research has shown that change in variety and/or field conditions can affect yield data quality, therefore additional calibration checks may be required in these situations to maintain data accuracy and quality. Yield data should be exported and transferred to a computer or cloud storage immediately after finishing the harvest.

Both Case and John Deere have developed cotton pickers with on-board capacity to construct modules or something similar. John Deere also offers on-board module weighing system and moisture sensing capabilities on their new CP690 cotton pickers that can provide individual round module weights and moisture content during harvest. Preliminary evaluation work conducted from 2018 to 2020 suggested that the accuracy of the on-board module weighing system was consistently above 90% when compared to a calibrated platform scale. The system needs to be calibrated properly before harvest and the cotton picker needs to be stopped completely when module is finished and weighed. Further research is on-going to determine the increased efficiencies associated with these new technologies. Preliminary observations suggest that some types of these pickers may reduce waste, may reduce trash from soil, stubble or grasses, and may preserve some yield and fiber quality characteristics.

Contamination Free Cotton

High yields and superior fiber quality are goals that all Georgia cotton producers strive to achieve, therefore awareness and prevention of lint contamination ensure that potential risks are avoided and that our products remain marketable. Cotton producers are competing with man-made fibers and

foreign cotton in today's marketplace. One of cotton's greatest attributes, its pure and natural quality, can be degraded by a variety of contaminants. This impairs producers' relationships with textile manufacturers and also undermines the industry's "value added" promotion activities.

Each year as cotton harvest season begins, it is important that producers have to be vigilant to keep contaminants out of their cotton. There have been reports of bales being sent back to gins, and customers moving elsewhere because of plastic issues. The cotton industry is committed to improving this situation for all along the cotton supply chain.

Foreign materials are simply anything but lint and seed that is mixed into the cotton during harvest or during or after processing. Contaminants can range from bark to plastic bags to bale wrap. Not only can foreign materials inadvertently make it into yarns and fabrics, but they can also degrade the crop. These things can very easily be taken in by harvesting equipment.

Always remember: it is easier to prevent contamination than it is to remove contaminants from baled or ginned cotton.

Consider the following:

Educate. Before harvest, growers should educate employees by creating a foreign material watch list, and posting that list in farm equipment cabs. Once that education is complete, workers can then identify and abate any potential contaminants in the field by stopping what they are doing to remove the foreign materials in the field.

Start Clean. Begin the harvest season with clean equipment. For growers who use the new picker/balers, it is important to make sure that the equipment is not rubbing or puncturing the bale wrap and that the wrap is adhering in the correct places, as to not have any yellow or pink plastic lodged in the cotton.

During Harvest. Crews must understand the consequences of allowing harvesting equipment to pick up foreign material. Be sure to inspect equipment daily and do not allow modules to be built or placed in areas where potential contaminations will be picked up with modules. Do not drop or build modules in standing or shredded stalks. Use a method to identify modules without marking seed cotton. Keep modules elevated. Transport modules at a height above cotton stalks and place them at a flat, clean spot with a bit of space between them.
them.

ATTENTION!
PESTICIDE PRECAUTIONS

- 1. Observe all directions, restrictions and precautions on pesticide labels. It is dangerous, wasteful, and illegal to do otherwise.**
- 2. Store all pesticides in original containers with labels intact and behind locked doors. "KEEP PESTICIDES OUT OF THE REACH OF CHILDREN."**
- 3. Use pesticides at correct label dosage and intervals to avoid illegal residues or injury to plants and animals.**
- 4. Apply pesticides carefully to avoid drift or contamination of non-target areas.**
- 5. Surplus pesticides and containers should be disposed of in accordance with label instructions so that contamination of water and other hazards will not result.**
- 6. Follow directions on the pesticide label regarding restrictions as required by State or Federal Laws and Regulations.**
- 7. Avoid any action that may threaten an Endangered Species or its habitat. Your county Extension agent can inform you of Endangered Species in your area, help you identify them, and through the Fish and Wildlife Service Field Office identify actions that may threaten Endangered Species or their habitat.**
